# ACKNOWLEDGMENTS

---

Grateful acknowledgment is hereby made of an indebtedness to those who have contributed to previous editions and whose compilations continue in use in this edition. In particular, acknowledgment is made of the contribution of L. P. Buseth, who prepared the conversion tables for the thirteenth edition and who prepared the table on the U.S. Standard Sieve Series.

---

## ABOUT THE EDITOR

---

John A. Dean assumed the editorship of *Lange's Handbook of Chemistry* in 1968 with the Eleventh Edition. He is currently Professor Emeritus of Chemistry at the University of Tennessee at Knoxville. The author of nine major chemistry reference books used throughout the world, John Dean's research interests, reflected in over 105 research papers and scholarly publications, include instrumental methods of analysis, flame emission and atomic absorption spectroscopy, chromatographic and solvent extraction methods, and polarography. He received his B.S., M.S., and Ph.D. in Chemistry from the University of Michigan at Ann Arbor. In 1974, he was given the Charles H. Stone Award by the Carolina-Piedmont Section of the American Chemical Society. In 1991, he was awarded the Distinguished Service Award by the Society for Applied Spectroscopy; by the same organization he was awarded Honorary Membership in 1997.

---

# PREFACE TO FIFTEENTH EDITION

---

This new edition, the fifth under the aegis of the present editor, remains the one-volume source of factual information for chemists, both professionals and students—the first place in which to “look it up” on the spot. The aim is to provide sufficient data to satisfy all one’s general needs without recourse to other reference sources. A user will find this volume of value as a time-saver because of the many tables of numerical data which have been especially compiled.

Descriptive properties for a basic group of approximately 4300 organic compounds are compiled in Section 1, an increase of 300 entries. All entries are listed alphabetically according to the senior prefix of the name. The data for each organic compound include (where available) name, structural formula, formula weight, Beilstein reference (or if unavailable, the entry to the *Merck Index*, 12th ed.), density, refractive index, melting point, boiling point, flash point, and solubility (citing numerical values if known) in water and various common organic solvents. Structural formulas either too complex or too ambiguous to be rendered as line formulas are grouped at the bottom of each facing double page on which the entries appear. Alternative names, as well as trivial names of long-standing usage, are listed in their respective alphabetical order at the bottom of each double page in the regular alphabetical sequence. Another feature that assists the user in locating a desired entry is the empirical formula index.

Section 2 on General Information, Conversion Tables, and Mathematics has had the table on general conversion factors thoroughly reworked. Similarly the material on Statistics in Chemical Analysis has had its contents more than doubled.

Descriptive properties for a basic group of inorganic compounds are compiled in Section 3, which has undergone a small increase in the number of entries. Many entries under the column “Solubility” supply the reader with precise quantities dissolved in a stated solvent and at a given temperature.

Several portions of Section 4, Properties of Atoms, Radicals, and Bonds, have been significantly enlarged. For example, the entries under “Ionization Energy of Molecular and Radical Species” now number 740 and have an additional column with the enthalpy of formation of the ions. Likewise, the table on “Electron Affinities of the Elements, Molecules, and Radicals” now contains about 225 entries. The Table of Nuclides has material on additional radionuclides, their radiations, and the neutron capture cross sections.

Revised material for Section 5 includes the material on surface tension, viscosity, dielectric constant, and dipole moment for organic compounds. In order to include more data at several temperatures, the material has been divided into two separate tables. Material on surface tension and viscosity constitute the first table with 715 entries; included is the temperature range of the liquid phase. Material on dielectric constant and dipole

moment constitute another table of 1220 entries. The additional data at two or more temperatures permit interpolation for intermediate temperatures and also permit limited extrapolation of the data. The Properties of Combustible Mixtures in Air has been revised and expanded to include over 450 compounds. Flash points are to be found in Section 1. Completely revised are the tables on Thermal Conductivity for gases, liquids, and solids. Van der Waals' constants for gases has been brought up to date and expanded to over 500 substances.

Section 6, which includes Enthalpies and Gibbs Energies of Formation, Entropies, and Heat Capacities of Organic and Inorganic Compounds, and Heats of Melting, Vaporization, and Sublimation and Specific Heat at Various Temperatures for organic and inorganic compounds, has expanded by 11 pages, but the major additions have involved data in columns where it previously was absent. More material has also been included for critical temperature, critical pressure, and critical volume.

The section on Spectroscopy has been retained but with some revisions and expansion. The section includes ultraviolet-visible spectroscopy, fluorescence, infrared and Raman spectroscopy, and X-ray spectrometry. Detection limits are listed for the elements when using flame emission, flame atomic absorption, electrothermal atomic absorption, argon induction coupled plasma, and flame atomic fluorescence. Nuclear magnetic resonance embraces tables for the nuclear properties of the elements, proton chemical shifts and coupling constants, and similar material for carbon-13, boron-11, nitrogen-15, fluorine-19, silicon-29, and phosphorus-31.

In Section 8, the material on solubility constants has been doubled to 550 entries. Sections on proton transfer reactions, including some at various temperatures, formation constants of metal complexes with organic and inorganic ligands, buffer solutions of all types, reference electrodes, indicators, and electrode potentials are retained with some revisions. The material on conductances has been revised and expanded, particularly in the table on limiting equivalent ionic conductances.

Everything in Sections 9 and 10 on physiochemical relationships, and on polymers, rubbers, fats, oils, and waxes, respectively, has been retained.

Section 11, Practical Laboratory Information, has undergone significant changes and expansion. Entries in the table on "Molecular Elevation of the Boiling Point" have been increased. McReynolds' constants for stationary phases in gas chromatography have been reorganized and expanded. The guide to ion-exchange resins and discussion is new and embraces all types of column packings and membrane materials. Gravimetric factors have been altered to reflect the changes in atomic weights for several elements. Newly added are tables listing elements precipitated by general analytical reagents, and giving equations for the redox determination of the elements with their equivalent weights. Discussion on the topics of precipitation and complexometric titrations include primary standards and indicators for each analytical technique. A new topic of masking and demasking agents includes discussion and tables of masking agents for various elements, for anions and neutral molecules, and common demasking agents. A table has been added listing the common amino acids with their pI and  $pK_a$  values and their 3-letter and 1-letter abbreviations. Lastly a 9-page table lists the threshold limit value (TLV) for gases and vapors.

As stated in earlier prefaces, every effort has been made to select the most useful and reliable information and to record it with accuracy. However, the editor's 50 years of

involvement with textbooks and handbooks bring a realization of the opportunities for gremlins to exert their inevitable mischief. It is hoped that users of this handbook will continue to offer suggestions of material that might be included in, or even excluded from, future editions and call attention to errors. These communications should be directed to the editor. The street address will change early in 1999, as will the telephone number. However, the e-mail address should remain as “pd105@aol.com.”

*John A. Dean*

---

# PREFACE TO FOURTEENTH EDITION

---

Perhaps it would be simplest to begin by stating the ways in which this new edition, the fourth under the aegis of the present editor, has *not* been changed. It remains the one-volume source of factual information for chemists, both professionals and students—the first place in which to “look it up” on the spot. The aim is to provide sufficient data to satisfy all one’s general needs without recourse to other reference sources. Even the worker with the facilities of a comprehensive library will find this volume of value as a time-saver because of the many tables of numerical data which have been especially compiled.

The changes, however, are both numerous and significant. First of all, there is a change in the organization of the subject matter. For example, material formerly contained in the section entitled Analytical Chemistry is now grouped by operational categories: spectroscopy; electrolytes, electromotive force, and chemical equilibrium; and practical laboratory information. Polymers, rubbers, fats, oils, and waxes constitute a large independent section.

Descriptive properties for a basic group of approximately 4000 organic compounds are compiled in Section 1. These follow a concise introduction to organic nomenclature, including the topic of stereochemistry. Nomenclature is consistent with the 1979 rules of the Commission on Nomenclature, International Union of Pure and Applied Chemistry (IUPAC). All entries are listed alphabetically according to the senior prefix of the name. The data for each organic compound include (where available) name, structural formula, formula weight, Beilstein reference, density, refractive index, melting point, boiling point, flash point, and solubility (citing numerical values if known) in water and various common organic solvents. Structural formulas either too complex or too ambiguous to be rendered as line formulas are grouped at the bottom of the page on which the entries appear. Alternative names, as well as trivial names of long-standing usage, are listed in their respective alphabetical order at the bottom of each page in the regular alphabetical sequence. Another feature that assists the user in locating a desired entry is the empirical formula index.

Section 2 combines the former separate section on Mathematics with the material involving General Information and Conversion Tables. The fundamental physical constants reflect values recommended in 1986. Physical and chemical symbols and definitions have undergone extensive revision and expansion. Presented in 14 categories, the entries follow recommendations published in 1988 by the IUPAC. The table of abbreviations and standard letter symbols provides, in a sense, an alphabetical index to the foregoing tables. The table of conversion factors has been modified in view of recent data and inclusion of SI units; cross-entries for “archaic” or unusual entries have been curtailed.

Descriptive properties for a basic group of approximately 1400 inorganic compounds are compiled in Section 3. These follow a concise, revised introduction to inorganic nomenclature that follows the recommendations of the IUPAC published in 1990. In this section are given the exact atomic (or formula) weight of the elements accompanied, when available, by the uncertainty in the final figure given in parentheses.

In Section 4 the data on bond lengths and strengths have been vastly increased so as to include not only the atomic and effective ionic radii of elements and the covalent radii for atoms, but also the bond lengths between carbon and other elements and between elements other than carbon. All

lengths are given in picometers (SI unit). Effective ionic radii are tabulated as a function of ion charge and coordination number. Bond dissociation energies are given in kilojoules per mole with the uncertainty of the final figure(s) given in parentheses when known. New tables include bond dipole moments, group dipole moments, work functions of the elements, and relative abundances of the naturally occurring elements. The table of nuclides has been shortened and includes only the more commonly encountered nuclides; tabulations list half-life, natural abundance, cross-section to thermal neutrons, and radiation emitted upon disintegration. Entries have been updated.

Revised material in Section 5 includes an extensive tabulation of binary and ternary azeotropes comprising approximately 850 entries. Over 975 compounds have values listed for viscosity, dielectric constant, dipole moment, and surface tension. Whenever possible, data for viscosity and dielectric constant are provided at two temperatures to permit interpolation for intermediate temperatures and also to permit limited extrapolation of the data. The dipole moments are often listed for different physical states. Values for surface tension can be calculated over a range of temperatures from two constants that can be fitted into a linear equation. Also extensively revised and expanded are the properties of combustible mixtures in air. A table of triple points has been added.

The tables in Section 6 contain values of the enthalpy and Gibbs energy of formation, entropy, and heat capacity at five temperatures for approximately 2000 organic compounds and 1500 inorganic compounds, many in more than one physical state. Separate tabulations have enthalpies of melting, vaporization, transition, and sublimation for organic and inorganic compounds. All values are given in SI units (joule) and have been extracted from the latest sources such as *JANAF Thermochemical Tables*, 3d ed. (1986); *Thermochemical Data of Organic Compounds*, 2d ed. (1986); and *Enthalpies of Vaporization of Organic Compounds*, published under the auspices of the IUPAC (1985). Also updated is the material on critical properties of elements and compounds.

The section on Spectroscopy has been expanded to include ultraviolet-visible spectroscopy, fluorescence, Raman spectroscopy, and mass spectroscopy. Retained sections have been thoroughly revised: in particular, the tables on electronic emission and atomic absorption spectroscopy, nuclear magnetic resonance, and infrared spectroscopy. Detection limits are listed for the elements when using flame emission, flame atomic absorption, electrothermal atomic absorption, argon ICP, and flame atomic fluorescence. Nuclear magnetic resonance embraces tables for the nuclear properties of the elements, proton chemical shifts and coupling constants, and similar material for carbon-13, boron-11, nitrogen-15, fluorine-19, silicon-29, and phosphorus-31.

Section 8 now combines all the material on electrolytes, electromotive force, and chemical equilibrium, some of which had formerly been included in the old "Analytical Chemistry" section of earlier editions. Material on the half-wave potentials of inorganic and organic materials has been thoroughly revised. The tabulation of the potentials of the elements and their compounds reflects recent IUPAC (1985) recommendations.

An extensive new Section 10 is devoted to polymers, rubbers, fats, oils, and waxes. A discussion of polymers and rubbers is followed by the formulas and key properties of plastic materials. For each member and type of the plastic families there is a tabulation of their physical, electrical, mechanical, and thermal properties and characteristics. A similar treatment is accorded the various types of rubber materials. Chemical resistance and gas permeability constants are also given for rubbers and plastics. The section concludes with various constants of fats, oils, and waxes.

The practical laboratory information contained in Section 11 has been gathered from many of the previous sections of earlier editions. This material has been supplemented with new material under separation methods, gravimetric and volumetric analysis, and laboratory solutions. Significant new tables under separation methods include: properties of solvents for chromatography, solvents having the same refractive index and the same density, McReynolds' constants for stationary phases in gas chromatography, characteristics of selected supercritical fluids, and typical performances in HPLC for various operating conditions. Under gravimetric and volumetric analysis, gravimetric factors, equations and equivalents for volumetric analysis, and titrimetric factors have been retained

along with the formation constants of EDTA metal complexes. In this age of awareness of chemical dangers, tables have been added for some common reactive and incompatible chemicals, chemicals recommended for refrigerated storage, and chemicals which polymerize or decompose on extended storage at low temperature. Updated is the information about the U.S. Standard Sieve Series. Thermometry data have been revised to bring them into agreement with the new International Temperature Scale–1990, and data for type N thermocouples are included.

Every effort has been made to select the most useful and most reliable information and to record it with accuracy. However, the editor's many years of involvement with handbooks bring a realization of the opportunities for gremlins to exert their inevitable mischief. It is hoped that users of this handbook will offer suggestions of material that might be included in, or even excluded from, future editions and call attention to errors. These communications should be directed to the editor at his home address (or by telephone).

*John A. Dean*

---

# PREFACE TO FIRST EDITION

---

This book is the result of a number of years' experience in the compiling and editing of data useful to chemists. In it an effort has been made to select material to meet the needs of chemists who cannot command the unlimited time available to the research specialist, or who lack the facilities of a large technical library which so often is not conveniently located at many manufacturing centers. If the information contained herein serves this purpose, the compiler will feel that he has accomplished a worthy task. Even the worker with the facilities of a comprehensive library may find this volume of value as a time-saver because of the many tables of numerical data which have been especially computed for this purpose.

Every effort has been made to select the most reliable information and to record it with accuracy. Many years of occupation with this type of work bring a realization of the opportunities for the occurrence of errors, and while every endeavor has been made to prevent them, yet it would be remarkable if the attempts towards this end had always been successful. In this connection it is desired to express appreciation to those who in the past have called attention to errors, and it will be appreciated if this be done again with the present compilation for the publishers have given their assurance that no expense will be spared in making the necessary changes in subsequent printings.

It has been aimed to produce a compilation complete within the limits set by the economy of available space. One difficulty always at hand to the compiler of such a book is that he must decide what data are to be excluded in order to keep the volume from becoming unwieldy because of its size. He can hardly be expected to have an expert's knowledge of all branches of the science nor the intuition necessary to decide in all cases which particular value to record, especially when many differing values are given in the literature for the same constant. If the expert in a particular field will judge the usefulness of this book by the data which it supplies to him from fields other than his specialty and not by the lack of highly specialized information in which only he and his co-workers are interested (and with which he is familiar and for which he would never have occasion to consult this compilation), then an estimate of its value to him will be apparent. However, if such specialists will call attention to missing data with which they are familiar and which they believe others less specialized will also need, then works of this type can be improved in succeeding editions.

Many of the gaps in this volume are caused by the lack of such information in the literature. It is hoped that to one of the most important classes of workers in chemistry, namely the teachers, the book will be of value not only as an aid in answering the most varied questions with which they are confronted by interested students, but also as an inspiration through what it suggests by the gaps and inconsistencies, challenging as they do the incentive to engage in the creative and experimental work necessary to supply the missing information.

While the principal value of the book is for the professional chemist or student of chemistry, it should also be of value to many people not especially educated as chemists. Workers in the natural sciences—physicists, mineralogists, biologists, pharmacists, engineers, patent attorneys, and librarians—are often called upon to solve problems dealing with the properties of chemical products or materials of construction. For such needs this compilation supplies helpful information and will serve not only as an economical substitute for the costly accumulation of a large library of monographs on specialized subjects, but also as a means of conserving the time required to search for

information so widely scattered throughout the literature. For this reason especial care has been taken in compiling a comprehensive index and in furnishing cross references with many of the tables.

It is hoped that this book will be of the same usefulness to the worker in science as is the dictionary to the worker in literature, and that its resting place will be on the desk rather than on the bookshelf.

### 1.1 NOMENCLATURE OF ORGANIC COMPOUNDS

---

The following synopsis of rules for naming organic compounds and the examples given in explanation are not intended to cover all the possible cases. For a more comprehensive and detailed description, see J. Rigaudy and S. P. Klesney, *Nomenclature of Organic Chemistry*, Sections A, B, C, D, E, F, and H, Pergamon Press, Oxford, 1979. This publication contains the recommendations of the Commission on Nomenclature of Organic Chemistry and was prepared under the auspices of the International Union of Pure and Applied Chemistry (IUPAC).

#### 1.1.1 Nonfunctional Compounds

**1.1.1.1 Alkanes.** The saturated open-chain (acyclic) hydrocarbons ( $C_nH_{2n+2}$ ) have names ending in -ane. The first four members have the trivial names *methane* ( $CH_4$ ), *ethane* ( $CH_3CH_3$  or  $C_2H_6$ ), *propane* ( $C_3H_8$ ), and *butane* ( $C_4H_{10}$ ). For the remainder of the alkanes, the first portion of the name

is derived from the Greek prefix (see Table 2.4) that cites the number of carbons in the alkane followed by -ane with elision of the terminal -a from the prefix, as shown in Table 1.1.

**TABLE 1.1** Names of Straight-Chain Alkanes

| $n^*$ | Name    | $n^*$ | Name        | $n^*$ | Name           | $n^*$ | Name            |
|-------|---------|-------|-------------|-------|----------------|-------|-----------------|
| 1     | Methane | 11    | Undecane‡   | 21    | Henicosane     | 60    | Hexacontane     |
| 2     | Ethane  | 12    | Dodecane    | 22    | Docosane       | 70    | Heptacontane    |

\*  $n$  = total number of carbon atoms.

† Formerly called enneane.

‡ Formerly called hendecane.

§ Formerly called eicosane.

For branching compounds, the parent structure is the longest continuous chain present in the compound. Consider the compound to have been derived from this structure by replacement of hydrogen by various alkyl groups. Arabic number prefixes indicate the carbon to which the alkyl group is attached. Start numbering at whichever end of the parent structure that results in the lowest-numbered locants. The arabic prefixes are listed in numerical sequence, separated from each other by commas and from the remainder of the name by a hyphen.

If the same alkyl group occurs more than once as a side chain, this is indicated by the prefixes di-, tri-, tetra-, etc. Side chains are cited in alphabetical order (before insertion of any multiplying prefix). The name of a complex radical (side chain) is considered to begin with the first letter of its complete name. Where names of complex radicals are composed of identical words, priority for citation is given to that radical which contains the lowest-numbered locant at the first cited point of difference in the radical. If two or more side chains are in equivalent positions, the one to be assigned the lowest-numbered locant is that cited first in the name. The complete expression for the side chain may be enclosed in parentheses for clarity or the carbon atoms in side chains may be indicated by primed locants.

If hydrocarbon chains of equal length are competing for selection as the parent, the choice goes in descending order to (1) the chain that has the greatest number of side chains, (2) the chain whose side chains have the lowest-numbered locants, (3) the chain having the greatest number of carbon atoms in the smaller side chains, or (4) the chain having the least-branched side chains.

These trivial names may be used for the unsubstituted hydrocarbon only:

Isobutane  $(\text{CH}_3)_2\text{CHCH}_3$

Neopentane  $(\text{CH}_3)_4\text{C}$

Isopentane  $(\text{CH}_3)_2\text{CHCH}_2\text{CH}_3$

Isohexane  $(\text{CH}_3)_2\text{CHCH}_2\text{CH}_2\text{CH}_3$

Univalent radicals derived from saturated unbranched alkanes by removal of hydrogen from a terminal carbon atom are named by adding -yl in place of -ane to the stem name. Thus the alkane

*ethane* becomes the radical *ethyl*. These exceptions are permitted for unsubstituted radicals only:

|                    |                                                 |                     |                                                       |
|--------------------|-------------------------------------------------|---------------------|-------------------------------------------------------|
| Isopropyl          | $(\text{CH}_3)_2\text{CH}-$                     | Isopentyl           | $(\text{CH}_3)_2\text{CHCH}_2\text{CH}_2-$            |
| Isobutyl           | $(\text{CH}_3)_2\text{CHCH}_2-$                 | Neopentyl           | $(\text{CH}_3)_3\text{CCH}_2-$                        |
| <i>sec</i> -Butyl  | $\text{CH}_3\text{CH}_2\text{CH}(\text{CH}_3)-$ | <i>tert</i> -Pentyl | $\text{CH}_3\text{CH}_2\text{C}(\text{CH}_3)_2-$      |
| <i>tert</i> -Butyl | $(\text{CH}_3)_3\text{C}-$                      | Isohexyl            | $(\text{CH}_3)_2\text{CHCH}_2\text{CH}_2\text{CH}_2-$ |

Note the usage of the prefixes *iso*-, *neo*-, *sec*-, and *tert*-, and note when italics are employed. Italicized prefixes are never involved in alphabetization, except among themselves; thus *sec*-butyl would precede isobutyl, isohexyl would precede isopropyl, and *sec*-butyl would precede *tert*-butyl.

Examples of alkane nomenclature are

4,4-Bis(1,1-dimethylethyl)-2-methyloctane

4,4-Bis-1',1'-dimethylethyl-2-methyloctane

4,4-Bis(*tert*-butyl)-2-methyloctane

Bivalent radicals derived from saturated unbranched alkanes by removal of two hydrogen atoms are named as follows: (1) If both free bonds are on the same carbon atom, the ending -ane of the hydrocarbon is replaced with -ylidene. However, for the first member of the alkanes it is methylene

rather than methyldiene. Isopropylidene, *sec*-butylidene, and neopentylidene may be used for the unsubstituted group only. (2) If the two free bonds are on different carbon atoms, the straight-chain group terminating in these two carbon atoms is named by citing the number of methylene groups comprising the chain. Other carbon groups are named as substituents. Ethylene is used rather than dimethylene for the first member of the series, and propylene is retained for  $\text{CH}_3\text{—CH—CH}_2\text{—}$  (but trimethylene is  $\text{—CH}_2\text{—CH}_2\text{—CH}_2\text{—}$ ).

Trivalent groups derived by the removal of three hydrogen atoms from the same carbon are named by replacing the ending -ane of the parent hydrocarbon with -ylidyne.

**1.1.1.2 Alkenes and Alkynes.** Each name of the corresponding saturated hydrocarbon is converted to the corresponding alkene by changing the ending -ane to -ene. For alkynes the ending is -yne. With more than one double (or triple) bond, the endings are -adiene, -atriene, etc. (or -adiyne, -atriyne, etc.). The position of the double (or triple) bond in the parent chain is indicated by a locant obtained by numbering from the end of the chain nearest the double (or triple) bond; thus  $\text{CH}_3\text{CH}_2\text{CH=CH}_2$  is 1-butene and  $\text{CH}_3\text{C}\equiv\text{CCH}_3$  is 2-butyne.

For multiple unsaturated bonds, the chain is so numbered as to give the lowest possible locants to the unsaturated bonds. When there is a choice in numbering, the double bonds are given the lowest locants, and the alkene is cited before the alkyne where both occur in the name. Examples:

Unsaturated branched acyclic hydrocarbons are named as derivatives of the chain that contains the maximum number of double and/or triple bonds. When a choice exists, priority goes in sequence to (1) the chain with the greatest number of carbon atoms and (2) the chain containing the maximum number of double bonds.

These nonsystematic names are retained:

An example of nomenclature for alkenes and alkynes is

Univalent radicals have the endings -enyl, -ynyl, -dienyl, -diynyl, etc. When necessary, the positions of the double and triple bonds are indicated by locants, with the carbon atom with the free valence numbered as 1. Examples:

These names are retained:

Vinyl (for ethenyl)  $\text{CH}_2=\text{CH}-$

Allyl (for 2-propenyl)  $\text{CH}_2=\text{CH}-\text{CH}_2-$

Isopropenyl (for 1-methylvinyl but for unsubstituted radical only)  $\text{CH}_2=\text{C}(\text{CH}_3)-$

Should there be a choice for the fundamental straight chain of a radical, that chain is selected which contains (1) the maximum number of double and triple bonds, (2) the largest number of carbon atoms, and (3) the largest number of double bonds. These are in descending priority.

Bivalent radicals derived from unbranched alkenes, alkadienes, and alkynes by removing a hydrogen atom from each of the terminal carbon atoms are named by replacing the endings -ene, -diene, and -yne by -enylene, -dienylene, and -ynylene, respectively. Positions of double and triple bonds are indicated by numbers when necessary. The name *vinylene* instead of ethenylene is retained for  $-\text{CH}=\text{CH}-$ .

**1.1.1.3 Monocyclic Aliphatic Hydrocarbons.** Monocyclic aliphatic hydrocarbons (with no side chains) are named by prefixing cyclo- to the name of the corresponding open-chain hydrocarbon having the same number of carbon atoms as the ring. Radicals are formed as with the alkanes, alkenes, and alkynes. Examples:

Cyclohexane

Cyclohexyl- (for the radical)

Cyclohexene

1-Cyclohexenyl- (for the radical with the free valence at carbon 1)

1,3-Cyclohexadiene

Cyclohexadienyl- (the unsaturated carbons are given numbers as low as possible, numbering from the carbon atom with the free valence given the number 1)

For convenience, aliphatic rings are often represented by simple geometric figures: a triangle for cyclopropane, a square for cyclobutane, a pentagon for cyclopentane, a hexagon (as illustrated) for cyclohexane, etc. It is understood that two hydrogen atoms are located at each corner of the figure unless some other group is indicated for one or both.

**1.1.1.4 Monocyclic Aromatic Compounds.** Except for six retained names, all monocyclic substituted aromatic hydrocarbons are named systematically as derivatives of benzene. Moreover, if the substituent introduced into a compound with a retained trivial name is identical with one already present in that compound, the compound is named as a derivative of benzene. These names are retained:

Cumene

Cymene (all three forms; *para*- shown)

Mesitylene

Styrene

Toluene

Xylene (all three  
forms; *meta*- shown)

The position of substituents is indicated by numbers, with the lowest locant possible given to substituents. When a name is based on a recognized trivial name, priority for lowest-numbered locants is given to substituents implied by the trivial name. When only two substituents are present on a benzene ring, their position may be indicated by *o*- (*ortho*-), *m*- (*meta*-), and *p*- (*para*-) (and alphabetized in the order given) used in place of 1,2-, 1,3-, and 1,4-, respectively.

Radicals derived from monocyclic substituted aromatic hydrocarbons and having the free valence at a ring atom (numbered 1) are named phenyl (for benzene as parent, since benzyl is used for the radical  $\text{C}_6\text{H}_5\text{CH}_2-$ ), cumenyl, mesityl, tolyl, and xylyl. All other radicals are named as substituted phenyl radicals. For radicals having a single free valence in the side chain, these trivial names are retained:

Benzyl  $\text{C}_6\text{H}_5\text{CH}_2-$

Phenethyl  $\text{C}_6\text{H}_5\text{CH}_2\text{CH}_2-$

Benzhydryl (alternative to  
diphenylmethyl)  $(\text{C}_6\text{H}_5)_2\text{CH}-$

Styryl  $\text{C}_6\text{H}_5\text{CH}=\text{CH}-$

Cinnamyl  $\text{C}_6\text{H}_5\text{CH}=\text{CH}-\text{CH}_2-$

Trityl  $(\text{C}_6\text{H}_5)_3\text{C}-$

Otherwise, radicals having the free valence(s) in the side chain are named in accordance with the rules for alkanes, alkenes, or alkynes.

The name *phenylene* (*o*-, *m*-, or *p*-) is retained for the radical  $-\text{C}_6\text{H}_4-$ . Bivalent radicals formed from substituted benzene derivatives and having the free valences at ring atoms are named as substituted phenylene radicals, with the carbon atoms having the free valences being numbered 1,2-, 1,3-, or 1,4-, as appropriate.

Radicals having three or more free valences are named by adding the suffixes -triyl, -tetrayl, etc. to the systematic name of the corresponding hydrocarbon.

**1.1.1.5 Fused Polycyclic Hydrocarbons.** The names of polycyclic hydrocarbons containing the maximum number of conjugated double bonds end in -ene. Here the ending does not denote one double bond. Names of hydrocarbons containing five or more fused benzene rings in a linear arrangement are formed from a numerical prefix (see Table 2.4) followed by -acene. A partial list of the names of polycyclic hydrocarbons is given in Table 1.2. Many names are trivial.

Numbering of each ring system is fixed, as shown in Table 1.2, but it follows a systematic pattern. The individual rings of each system are oriented so that the greatest number of rings are (1) in a horizontal row and (2) the maximum number of rings are above and to the right (upper-right quadrant) of the horizontal row. When two orientations meet these requirements, the one is chosen that has the fewest rings in the lower-left quadrant. Numbering proceeds in a clockwise direction, commencing with the carbon atom not engaged in ring fusion that lies in the most counterclockwise position of the uppermost ring (upper-right quadrant); omit atoms common to two or more rings. Atoms common to two or more rings are designated by adding lowercase roman letters to the number of the position immediately preceding. Interior atoms follow the highest number, taking a clockwise

sequence wherever there is a choice. Anthracene and phenanthrene are two exceptions to the rule on numbering. Two examples of numbering follow:

When a ring system with the maximum number of conjugated double bonds can exist in two or more forms differing only in the position of an “extra” hydrogen atom, the name can be made specific by indicating the position of the extra hydrogen(s). The compound name is modified with a locant followed by an italic capital *H* for each of these hydrogen atoms. Carbon atoms that carry an indicated hydrogen atom are numbered as low as possible. For example, 1*H*-indene is illustrated in Table 1.2; 2*H*-indene would be

Names of polycyclic hydrocarbons with less than the maximum number of noncumulative double bonds are formed from a prefix dihydro-, tetrahydro-, etc., followed by the name of the corresponding unreduced hydrocarbon. The prefix perhydro- signifies full hydrogenation. For example, 1,2-dihydronaphthalene is

Examples of retained names and their structures are as follows:

Indan

Acenaphthene

Aceanthrene

Acephenanthrene

Polycyclic compounds in which two rings have two atoms in common or in which one ring contains two atoms in common with each of two or more rings of a contiguous series of rings and which contain at least two rings of five or more members with the maximum number of noncumu-

**TABLE 1.2** Fused Polycyclic Hydrocarbons (*Continued*)

|                                                                                                           |                                                                                                          |
|-----------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| <p>17. Triphenylene</p>  | <p>19. Chrysene</p>     |
| <p>18. Pyrene</p>        | <p>20. Naphthacene</p>  |

lative double bonds and which have no accepted trivial name (Table 1.2) are named by prefixing to the name of the parent ring or ring system designations of the other components. The parent name should contain as many rings as possible (provided it has a trivial name) and should occur as far as possible from the beginning of the list in Table 1.2. Furthermore, the attached component(s) should be as simple as possible. For example, one writes dibenzophenanthrene and not naphthophenanthrene because the attached component benzo- is simpler than naphtho-. Prefixes designating attached components are formed by changing the ending -ene into -eno-; for example, indeno- from indene. Multiple prefixes are arranged in alphabetical order. Several abbreviated prefixes are recognized; the parent is given in parentheses:

Acenaphtho- (acenaphthylene)

Naphtho- (naphthalene)

Anthra- (anthracene)

Perylo- (perylene)

Benzo- (benzene)

Phenanthro- (phenanthrene)

For monocyclic prefixes other than benzo-, the following names are recognized, each to represent the form with the maximum number of noncumulative double bonds: cyclopenta-, cyclohepta-, cycloocta-, etc.

Isomers are distinguished by lettering the peripheral sides of the parent beginning with *a* for the side 1,2, and so on, lettering every side around the periphery. If necessary for clarity, the numbers of the attached position (1,2, for example) of the substituent ring are also denoted. The prefixes are cited in alphabetical order. The numbers and letters are enclosed in square brackets and placed immediately after the designation of the attached component. Examples are

Benz[ $\alpha$ ]anthraceneAnthra[2,1- $\alpha$ ]naphthacene

**1.1.1.6 Bridged Hydrocarbons.** Saturated alicyclic hydrocarbon systems consisting of two rings that have two or more atoms in common take the name of the open-chain hydrocarbon containing the same total number of carbon atoms and are preceded by the prefix bicyclo-. The system is numbered commencing with one of the bridgeheads, numbering proceeding by the longest possible path to the second bridgehead. Numbering is then continued from this atom by the longer remaining unnumbered path back to the first bridgehead and is completed by the shortest path from the atom next to the first bridgehead. When a choice in numbering exists, unsaturation is given the lowest numbers. The number of carbon atoms in each of the bridges connecting the bridgeheads is indicated in brackets in descending order. Examples are

Bicyclo[3.2.1]octane

Bicyclo[5.2.0]nonane

**1.1.1.7 Hydrocarbon Ring Assemblies.** Assemblies are two or more cyclic systems, either single rings or fused systems, that are joined directly to each other by double or single bonds. For identical systems naming may proceed (1) by placing the prefix bi- before the name of the corresponding radical or (2), for systems joined through a single bond, by placing the prefix bi- before the name of the corresponding hydrocarbon. In each case, the numbering of the assembly is that of the corresponding radical or hydrocarbon, one system being assigned unprimed numbers and the other primed numbers. The points of attachment are indicated by placing the appropriate locants before the name; an unprimed number is considered lower than the same number primed. The name *biphenyl* is used for the assembly consisting of two benzene rings. Examples are

1,1'-Bicycloppropyl or 1,1'-bicyclopropane

2-Ethyl-2'-propylbiphenyl

For nonidentical ring systems, one ring system is selected as the parent and the other systems are considered as substituents and are arranged in alphabetical order. The parent ring system is assigned unprimed numbers. The parent is chosen by considering the following characteristics in turn until a decision is reached: (1) the system containing the larger number of rings, (2) the system containing the larger ring, (3) the system in the lowest state of hydrogenation, and (4) the highest-order number of ring systems set forth in Table 1.2. Examples are given, with the deciding priority given in parentheses preceding the name:

- (1) 2-Phenyl(naphthalene)
- (2) and (4) 2-(2'-Naphthyl)azulene
- (3) Cyclohexylbenzene

**1.1.1.8 Radicals from Ring Systems.** Univalent substituent groups derived from polycyclic hydrocarbons are named by changing the final *e* of the hydrocarbon name to -yl. The carbon atoms having free valences are given locants as low as possible consistent with the fixed numbering of the

hydrocarbon. Exceptions are naphthyl (instead of naphthalenyl), anthryl (for anthracenyl), and phenanthryl (for phenanthrenyl). However, these abbreviated forms are used only for the simple ring systems. Substituting groups derived from fused derivatives of these ring systems are named systematically. Substituting groups having two or more free bonds are named as described in Monocyclic Aliphatic Hydrocarbons on p. 1.5.

**1.1.1.9 Cyclic Hydrocarbons with Side Chains.** Hydrocarbons composed of cyclic and aliphatic chains are named in a manner that is the simplest permissible or the most appropriate for the chemical intent. Hydrocarbons containing several chains attached to one cyclic nucleus are generally named as derivatives of the cyclic compound, and compounds containing several side chains and/or cyclic radicals attached to one chain are named as derivatives of the acyclic compound. Examples are

2-Ethyl-1-methylnaphthalene

Diphenylmethane

1,5-Diphenylpentane

2,3-Dimethyl-1-phenyl-1-hexene

Recognized trivial names for composite radicals are used if they lead to simplifications in naming. Examples are

1-Benzyl-naphthalene

1,2,4-Tris(3-*p*-tolylpropyl)benzene

Fulvene, for methylenecyclopentadiene, and stilbene, for 1,2-diphenylethylene, are trivial names that are retained.

**1.1.1.10 Heterocyclic Systems.** Heterocyclic compounds can be named by relating them to the corresponding carbocyclic ring systems by using replacement nomenclature. Heteroatoms are denoted by prefixes ending in *a*, as shown in Table 1.3. If two or more replacement prefixes are required in a single name, they are cited in the order of their listing in the table. The lowest possible numbers consistent with the numbering of the corresponding carbocyclic system are assigned to the heteroatoms and then to carbon atoms bearing double or triple bonds. Locants are cited immediately preceding the prefixes or suffixes to which they refer. Multiplicity of the same heteroatom is indicated by the appropriate prefix in the series: di-, tri-, tetra-, penta-, hexa-, etc.

**TABLE 1.3** Specialist Nomenclature for Heterocyclic Systems

*Heterocyclic atoms are listed in decreasing order of priority.*

| Element    | Valence | Prefix    | Element   | Valence | Prefix   |
|------------|---------|-----------|-----------|---------|----------|
| Oxygen     | 2       | Oxa-      | Antimony  | 3       | Stiba-*  |
| Sulfur     | 2       | Thia-     | Bismuth   | 3       | Bisma-   |
| Selenium   | 2       | Selena-   | Silicon   | 4       | Sila-    |
| Tellurium  | 2       | Tellura-  | Germanium | 4       | Germa-   |
| Nitrogen   | 3       | Aza-      | Tin       | 4       | Stanna-  |
| Phosphorus | 3       | Phospha-* | Lead      | 4       | Plumba-  |
| Arsenic    | 3       | Arsa-*    | Boron     | 3       | Bora-    |
|            |         |           | Mercury   | 2       | Mercura- |

\* When immediately followed by -in or -ine, phospha- should be replaced by phosphor-, arsa- by arsen-, and stiba- by antimon-. The saturated six-membered rings corresponding to phosphorin and arsenin are named *phosphorinane* and *arsenane*. A further exception is the replacement of borin by borinane.

**TABLE 1.4** Suffixes for Specialist Nomenclature of Heterocyclic Systems

| Number of ring members | Rings containing nitrogen |            | Rings containing no nitrogen |            |
|------------------------|---------------------------|------------|------------------------------|------------|
|                        | Unsaturation*             | Saturation | Unsaturation*                | Saturation |
| 3                      | -irine                    | -iridine   | -irene                       | -irane     |
| 4                      | -ete                      | -etidine   | -ete                         | -etane     |
| 5                      | -ole                      | -olidine   | -ole                         | -olane     |
| 6                      | -ine†                     | ‡          | -in                          | -ane§      |
| 7                      | -epine                    | ‡          | -epin                        | -epane     |
| 8                      | -ocine                    | ‡          | -ocin                        | -ocane     |
| 9                      | -onine                    | ‡          | -onin                        | -onane     |
| 10                     | -ecine                    | ‡          | -ecin                        | -ecane     |

\* Unsaturation corresponding to the maximum number of noncumulative double bonds. Heteroatoms have the normal valences given in Table 1.3.

† For phosphorus, arsenic, antimony, and boron, see the special provisions in Table 1.3.

‡ Expressed by prefixing perhydro- to the name of the corresponding unsaturated compound.

§ Not applicable to silicon, germanium, tin, and lead; perhydro- is prefixed to the name of the corresponding unsaturated compound.

If the corresponding carbocyclic system is partially or completely hydrogenated, the additional hydrogen is cited using the appropriate *H*- or hydro- prefixes. A trivial name from Tables 1.5 and 1.6, if available, along with the state of hydrogenation may be used. In the specialist nomenclature for heterocyclic systems, the prefix or prefixes from Table 1.3 are combined with the appropriate stem from Table 1.4, eliding an *a* where necessary. Examples of acceptable usage, including (1) replacement and (2) specialist nomenclature, are

- (1) 1-Oxa-4-azacyclohexane  
(2) 1,4-Oxazoline  
Morpholine

- (1) 1,3-Diazacyclohex-5-ene  
(2) 1,2,3,4-Tetrahydro-1,3-diazine

- (1) Thiacyclopropane  
(2) Thiirane  
Ethylene sulfide

Radicals derived from heterocyclic compounds by removal of hydrogen from a ring are named by adding -yl to the names of the parent compounds (with elision of the final *e*, if present). These exceptions are retained:

Furyl (from furan)

Pyridyl (from pyridine)

Piperidyl (from piperidine)

Quinolyl (from quinoline)

Isoquinolyl

Thenylidene (for thienylmethylene)

Furfuryl (for 2-furylmethyl)

Furfurylidene (for 2-furylmethylene)

Thienyl (from thiophene)

Thenylidyne (for thienylmethyldiyne)

Furfuryldiyne (for 2-furylmethyldiyne)

Thenyl (for thienylmethyl)

Also, piperidino- and morpholino- are preferred to 1-piperidyl- and 4-morpholinyl-, respectively.

\* Asterisk after a compound denotes exception to systematic numbering.

If there is a choice among heterocyclic systems, the parent compound is decided in the following order of preference:

1. A nitrogen-containing component
2. A component containing a heteroatom, in the absence of nitrogen, as high as possible in Table 1.3
3. A component containing the greater number of rings

**TABLE 1.6** Trivial Names of Heterocyclic Systems That Are Not Recommended for Use in Fusion Names  
Listed in order of increasing priority.

| Structure | Parent name               | Radical name   | Structure | Parent name              | Radical name  |
|-----------|---------------------------|----------------|-----------|--------------------------|---------------|
|           | Isochroman                | Isochromanyl   |           | Pyrazoline<br>(3-shown*) | Pyrazolinyl   |
|           | Chroman                   | Chromanyl      |           | Piperidine               | Piperidyl†    |
|           | Pyrrolidine               | Pyrrolinyl     |           | Piperazine               | Piperazinyl   |
|           | Pyrroline<br>(2-shown*)   | Pyrrolinyl     |           | Indoline                 | Indolinyl     |
|           | Imidazolidine             | Imidazolidinyl |           | Isoindoline              | Isoindolinyl  |
|           | Imidazoline<br>(2-shown*) | Imidazoliny    |           | Quinuclidine             | Quinuclidinyl |
|           | Pyrazolidine              | Pyrazolidinyl  |           | Morpholine               | Morpholinyl‡  |

\* Denotes position of double bond.

† For 1-piperidyl, use piperidino.

‡ For 4-morpholinyl, use morpholino.

- A component containing the largest possible individual ring
- A component containing the greatest number of heteroatoms of any kind
- A component containing the greatest variety of heteroatoms
- A component containing the greatest number of heteroatoms first listed in Table 1.3

If there is a choice between components of the same size containing the same number and kind of heteroatoms, choose as the base component that one with the lower numbers for the heteroatoms before fusion. When a fusion position is occupied by a heteroatom, the names of the component rings to be fused are selected to contain the heteroatom.

### 1.1.2 Functional Compounds

There are several types of nomenclature systems that are recognized. Which type to use is sometimes obvious from the nature of the compound. Substitutive nomenclature, in general, is preferred because of its broad applicability, but radicofunctional, additive, and replacement nomenclature systems are convenient in certain situations.

**1.1.2.1 Substitutive Nomenclature.** The first step is to determine the kind of characteristic (functional) group for use as the principal group of the parent compound. A characteristic group is a recognized combination of atoms that confers characteristic chemical properties on the molecule in which it occurs. Carbon-to-carbon unsaturation and heteroatoms in rings are considered nonfunctional for nomenclature purposes.

*Substitution* means the replacement of one or more hydrogen atoms in a given compound by some other kind of atom or group of atoms, functional or nonfunctional. In substitutive nomenclature, each substituent is cited as either a prefix or a suffix to the name of the parent (or substituting radical) to which it is attached; the latter is denoted the parent compound (or parent group if a radical).

In Table 1.7 are listed the general classes of compounds in descending order of preference for citation as suffixes, that is, as the parent or characteristic compound. When oxygen is replaced by sulfur, selenium, or tellurium, the priority for these elements is in the descending order listed. The higher valence states of each element are listed before considering the successive lower valence states. Derivative groups have priority for citation as principal group after the respective parents of their general class.

In Table 1.8 are listed characteristic groups that are cited only as prefixes (never as suffixes) in substitutive nomenclature. The order of listing has no significance for nomenclature purposes.

Systematic names formed by applying the principles of substitutive nomenclature are single words except for compounds named as acids. First one selects the parent compound, and thus the suffix, from the characteristic group listed earliest in Table 1.7. All remaining functional groups are handled as prefixes that precede, in alphabetical order, the parent name. Two examples may be helpful:

Structure I

Structure II

Structure I contains an ester group and an ether group. Since the ester group has higher priority, the name is ethyl 2-methoxy-6-methyl-3-cyclohexene-1-carboxylate. Structure II contains a carbonyl group, a hydroxy group, and a bromo group. The latter is never a suffix. Between the other two, the carbonyl group has higher priority, the parent has -one as suffix, and the name is 4-bromo-1-hydroxy-2-butanone.

Selection of the principal alicyclic chain or ring system is governed by these selection rules:

1. For purely alicyclic compounds, the selection process proceeds successively until a decision is reached: (a) the maximum number of substituents corresponding to the characteristic group cited earliest in Table 1.7, (b) the maximum number of double and triple bonds considered together, (c) the maximum length of the chain, and (d) the maximum number of double bonds. Additional criteria, if needed for complicated compounds, are given in the IUPAC nomenclature rules.
2. If the characteristic group occurs only in a chain that carries a cyclic substituent, the compound is named as an aliphatic compound into which the cyclic component is substituted; a radical prefix is used to denote the cyclic component. This chain need not be the longest chain.
3. If the characteristic group occurs in more than one carbon chain and the chains are not directly

**TABLE 1.7** Characteristic Groups for Substitutive Nomenclature

Listed in order of decreasing priority for citation as principal group or parent name.

| Class                    | Formula*                                                                                                                                                                              | Prefix                                                                                          | Suffix                                                                                                 |

**TABLE 1.7** Characteristic Groups for Substitutive Nomenclature (*Continued*)

| Class                        | Formula*                             | Prefix                  | Suffix          |
|------------------------------|--------------------------------------|-------------------------|-----------------|
| Hydrazides                   | $\text{—CO—NHNH}_2$                  | Carbonyl-<br>hydrazino- | -carbohydrazide |
| Imides                       | $\text{—(CO)—NHNH}_2$                |                         | -ohydrazide     |
| Amidines                     | $\text{—CO—NH—CO—}$                  | R-imido-                | -carboximide    |
|                              | $\text{—C(=NH)—NH}_2$                | Amidino-                | -carboxamidine  |
|                              | $\text{—(C=NH)—NH}_2$                |                         | -amidine        |
| 4. Nitrile (cyanide)         | $\text{—CN}$                         | Cyano-                  | -carbonitrile   |
|                              | $\text{—(C)N}$                       |                         | -nitrile        |
| 5. Aldehydes                 | $\text{—CHO}$                        | Formyl-                 | -carbaldehyde   |
|                              | $\text{—(C=O)H}$                     | Oxo-                    | -al             |
|                              | (then their analogs and derivatives) |                         |                 |
| 6. Ketones                   | $\text{>(C=O)}$                      | Oxo-                    | -one            |
|                              | (then their analogs and derivatives) |                         |                 |
| 7. Alcohols<br>(and phenols) | $\text{—OH}$                         | Hydroxy-                | -ol             |
| Thiols                       | $\text{—SH}$                         | Mercapto-               | -thiol          |
| 8. Hydroperoxides            | $\text{—O—OH}$                       | Hydroperoxy-            |                 |
| 9. Amines                    | $\text{—NH}_2$                       | Amino-                  | -amine          |
| Imines                       | $\text{>NH}$                         | Imino-                  | -imine          |
| Hydrazines                   | $\text{—NHNH}_2$                     | Hydrazino-              | -hydrazine      |
| 10. Ethers                   | $\text{—OR}$                         | R-oxy-                  |                 |
| Sulfides                     | $\text{—SR}$                         | R-thio-                 |                 |
| 11. Peroxides                | $\text{—O—OR}$                       | R-dioxy-                |                 |

\* Carbon atoms enclosed in parentheses are included in the name of the parent compound and not in the suffix or prefix.

**TABLE 1.8** Characteristic Groups Cited Only as Prefixes in Substitutive Nomenclature

| Characteristic group | Prefix         | Characteristic group | Prefix                                                                                                   |
|----------------------|----------------|----------------------|----------------------------------------------------------------------------------------------------------|
| $\text{—Br}$         | Bromo-         | $\text{—IX}_2$       | X may be halogen or a radical; dihalogenoiodo- or diacetoxyiodo-, e.g., $\text{—ICl}_2$ is dichloroiodo- |
| $\text{—Cl}$         | Chloro-        |                      |                                                                                                          |
| $\text{—ClO}$        | Chlorosyl-     | $\text{>N}_2$        | Diazo-                                                                                                   |
| $\text{—ClO}_2$      | Chloryl-       | $\text{—N}_3$        | Azido-                                                                                                   |
| $\text{—ClO}_3$      | Perchloryl-    | $\text{—NO}$         | Nitroso-                                                                                                 |
| $\text{—F}$          | Fluoro-        | $\text{—NO}_2$       | Nitro-                                                                                                   |
| $\text{—I}$          | Iodo-          | $\text{>N(=O)OH}$    | <i>aci</i> -Nitro-                                                                                       |
| $\text{—IO}$         | Iodosyl-       | $\text{—OR}$         | R-oxy-                                                                                                   |
| $\text{—IO}_2$       | Iodyl*         | $\text{—SR}$         | R-thio-                                                                                                  |
| $\text{—I(OH)}_2$    | Dihydroxyiodo- | $\text{—SeR (—TeR)}$ | R-seleno- (R-telluro-)                                                                                   |

\* Formerly iodoxy.

attached to one another, then the chain chosen as parent should carry the largest number of the characteristic group. If necessary, the selection is continued as in rule 1.

4. If the characteristic group occurs only in one cyclic system, that system is chosen as the parent.
5. If the characteristic group occurs in more than one cyclic system, that system is chosen as parent which (a) carries the largest number of the principal group or, failing to reach a decision, (b) is the senior ring system.
6. If the characteristic group occurs both in a chain and in a cyclic system, the parent is that portion in which the principal group occurs in largest number. If the numbers are the same, that portion is chosen which is considered to be the most important or is the senior ring system.
7. When a substituent is itself substituted, all the subsidiary substituents are named as prefixes and the entire assembly is regarded as a parent radical.
8. The seniority of ring systems is ascertained by applying the following rules successively until a decision is reached: (a) all heterocycles are senior to all carbocycles, (b) for heterocycles, the preference follows the decision process described under Heterocyclic Systems, p. 1.11, (c) the largest number of rings, (d) the largest individual ring at the first point of difference, (e) the largest number of atoms in common among rings, (f) the lowest letters in the expression for ring functions, (g) the lowest numbers at the first point of difference in the expression for ring junctions, (h) the lowest state of hydrogenation, (i) the lowest-numbered locant for indicated hydrogen, (j) the lowest-numbered locant for point of attachment (if a radical), (k) the lowest-numbered locant for an attached group expressed as a suffix, (l) the maximum number of substituents cited as prefixes, (m) the lowest-numbered locant for substituents named as prefixes, hydro prefixes, -ene, and -yne, all considered together in one series in ascending numerical order independent of their nature, and (n) the lowest-numbered locant for the substituent named as prefix which is cited first in the name.

*Numbering of Compounds.* If the rules for aliphatic chains and ring systems leave a choice, the starting point and direction of numbering of a compound are chosen so as to give lowest-numbered locants to these structural factors, if present, considered successively in the order listed below until a decision is reached. Characteristic groups take precedence over multiple bonds.

1. Indicated hydrogen, whether cited in the name or omitted as being conventional
2. Characteristic groups named as suffix following the ranking order of Table 1.7
3. Multiple bonds in acyclic compounds; in bicycloalkanes, tricycloalkanes, and polycycloalkanes, double bonds having priority over triple bonds; and in heterocyclic systems whose names end in -etine, -oline, or -olene
4. The lowest-numbered locant for substituents named as prefixes, hydro prefixes, -ene, and -yne, all considered together in one series in ascending numerical order
5. The lowest locant for that substituent named as prefix which is cited first in the name

For cyclic radicals, indicated hydrogen and thereafter the point of attachment (free valency) have priority for the lowest available number.

*Prefixes and Affixes.* Prefixes are arranged alphabetically and placed before the parent name; multiplying affixes, if necessary, are inserted and *do not* alter the alphabetical order already attained. The parent name includes any syllables denoting a change of ring member or relating to the structure of a carbon chain. Nondetachable parts of parent names include

1. Forming rings; cyclo-, bicyclo-, spiro-
2. Fusing two or more rings: benzo-, naphtho-, imidazo-
3. Substituting one ring or chain member atom for another: oxa-, aza-, thia-
4. Changing positions of ring or chain members: iso-, *sec*-, *tert*-, neo-
5. Showing indicated hydrogen
6. Forming bridges: ethano-, epoxy-
7. Hydro-

Prefixes that represent complete terminal characteristic groups are preferred to those representing only a portion of a given group. For example, for the prefix  $\text{—C(=O)CH}_3$ , the name (formylmethyl) is preferred to (oxoethyl).

The multiplying affixes di-, tri-, tetra-, penta-, hexa-, hepta-, octa-, nona-, deca-, undeca-, and so on are used to indicate a set of *identical* unsubstituted radicals or parent compounds. The forms bis-, tris-, tetrakis-, pentakis-, and so on are used to indicate a set of identical radicals or parent compounds *each substituted in the same way*. The affixes bi-, ter-, quater-, quinque-, sexi-, septi-, octi-, novi-, deci-, and so on are used to indicate the number of identical rings joined together by a single or double bond.

Although multiplying affixes may be omitted for very common compounds when no ambiguity is caused thereby, such affixes are generally included throughout this handbook in alphabetical listings. An example would be ethyl ether for diethyl ether.

**1.1.2.2 Conjunctive Nomenclature.** Conjunctive nomenclature may be applied when a principal group is attached to an acyclic component that is directly attached by a carbon-carbon bond to a cyclic component. The name of the cyclic component is attached directly in front of the name of the acyclic component carrying the principal group. This nomenclature is not used when an unsaturated side chain is named systematically. When necessary, the position of the side chain is indicated by a locant placed before the name of the cyclic component. For substituents on the acyclic chain, carbon atoms of the side chain are indicated by Greek letters proceeding from the principal group to the cyclic component. The terminal carbon atom of acids, aldehydes, and nitriles is omitted when allocating Greek positional letters. Conjunctive nomenclature is not used when the side chain carries more than one of the principal group, except in the case of malonic and succinic acids.

The side chain is considered to extend only from the principal group to the cyclic component. Any other chain members are named as substituents, with appropriate prefixes placed before the name of the cyclic component.

When a cyclic component carries more than one identical side chain, the name of the cyclic component is followed by di-, tri-, etc., and then by the name of the acyclic component, and it is preceded by the locants for the side chains. Examples are

When side chains of two or more different kinds are attached to a cyclic component, only the senior side chain is named by the conjunctive method. The remaining side chains are named as prefixes. Likewise, when there is a choice of cyclic component, the senior is chosen. Benzene derivatives may be named by the conjunctive method only when two or more identical side chains are present. Trivial names for oxo carboxylic acids may be used for the acyclic component. If the cyclic and acyclic components are joined by a double bond, the locants of this bond are placed as superscripts to a Greek capital delta that is inserted between the two names. The locant for the cyclic component precedes that for the acyclic component, e.g., indene- $\Delta^{1,\alpha}$ -acetic acid.

**1.1.2.3 Radicofunctional Nomenclature.** The procedures of radicofunctional nomenclature are identical with those of substitutive nomenclature except that suffixes are never used. Instead, the functional class name (Table 1.9) of the compound is expressed as one word and the remainder of the molecule as another that precedes the class name. When the functional class name refers to a characteristic group that is bivalent, the two radicals attached to it are each named, and when different, they are written as separate words arranged in alphabetical order. When a compound contains more than one kind of group listed in Table 1.9, that kind is cited as the functional group or class name that occurs higher in the table, all others being expressed as prefixes.

Radicofunctional nomenclature finds some use in naming ethers, sulfides, sulfoxides, sulfones, selenium analogs of the preceding three sulfur compounds, and azides.

**TABLE 1.9** Functional Class Names Used in Radicofunctional Nomenclature

*Groups are listed in order of decreasing priority.*

| Group                        | Functional class names                                                                                                   |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| X in acid derivatives        | Name of X (in priority order: fluoride, chloride, bromide, iodide, cyanide, azide; then the sulfur and selenium analogs) |
| —CN, —NC                     | Cyanide, isocyanide                                                                                                      |
| >CO                          | Ketone; then S and Se analogs                                                                                            |
| —OH                          | Alcohol; then S and Se analogs                                                                                           |
| —O—OH                        | Hydroperoxide                                                                                                            |
| >O                           | Ether or oxide                                                                                                           |
| >S, >SO, >SO <sub>2</sub>    | Sulfide, sulfoxide, sulfone                                                                                              |
| >Se, >SeO, >SeO <sub>2</sub> | Selenide, selenoxide, selenone                                                                                           |
| —F, —Cl, —Br, —I             | Fluoride, chloride, bromide, iodide                                                                                      |
| —N <sub>3</sub>              | Azide                                                                                                                    |

**1.1.2.4 Replacement Nomenclature.** Replacement nomenclature is intended for use only when other nomenclature systems are difficult to apply in the naming of chains containing heteroatoms. When no group is present that can be named as a principal group, the longest chain of carbon and heteroatoms terminating with carbon is chosen and named as though the entire chain were that of an acyclic hydrocarbon. The heteroatoms within this chain are identified by means of prefixes aza-, oxa-, thia-, etc., in the order of priority stated in Table 1.3. Locants indicate the positions of the heteroatoms in the chain. Lowest-numbered locants are assigned to the principal group when

such is present. Otherwise, lowest-numbered locants are assigned to the heteroatoms considered together and, if there is a choice, to the heteroatoms cited earliest in Table 1.3. An example is

13-Hydroxy-9,12-dioxa-3,6-diazatridecanoic acid

### 1.1.3 Specific Functional Groups

Characteristic groups will now be treated briefly in order to expand the terse outline of substitutive nomenclature presented in Table 1.7. Alternative nomenclature will be indicated whenever desirable.

**1.1.3.1 Acetals and Acylals.** Acetals, which contain the group  $>\text{C}(\text{OR})_2$ , where R may be different, are named (1) as dialkoxo compounds or (2) by the name of the corresponding aldehyde or ketone followed by the name of the hydrocarbon radical(s) followed by the word *acetal*. For example,  $\text{CH}_3-\text{CH}(\text{OCH}_3)_2$  is named either (1) 1,1-dimethoxyethane or (2) acetaldehyde dimethyl acetal.

A cyclic acetal in which the two acetal oxygen atoms form part of a ring may be named (1) as a heterocyclic compound or (2) by use of the prefix methylenedioxy for the group  $-\text{O}-\text{CH}_2-\text{O}-$  as a substituent in the remainder of the molecule. For example,

(1) 1,3-Benzo[d]dioxole-5-carboxylic acid

(2) 3,4-Methylenedioxybenzoic acid

Acylals,  $\text{R}^1\text{R}^2\text{C}(\text{OCOR}^3)_2$ , are named as acid esters;

Butylidene acetate  
propionate

$\alpha$ -Hydroxy ketones, formerly called acyloins, had been named by changing the ending -ic acid or -oic acid of the corresponding acid to -oin. They are preferably named by substitutive nomenclature; thus

**1.1.3.2 Acid Anhydrides.** Symmetrical anhydrides of monocarboxylic acids, when unsubstituted, are named by replacing the word *acid* by *anhydride*. Anhydrides of substituted monocarboxylic acids, if symmetrically substituted, are named by prefixing bis- to the name of the acid and replacing the word *acid* by *anhydride*. Mixed anhydrides are named by giving in alphabetical order the first part of the names of the two acids followed by the word *anhydride*, e.g., acetic propionic anhydride or acetic propanoic anhydride. Cyclic anhydrides of polycarboxylic acids, although possessing a

heterocyclic structure, are preferably named as acid anhydrides. For example,

1,8;4,5-Naphthalenetetracarboxylic dianhydride (note the use of a semicolon to distinguish the pairs of locants)

**1.1.3.3 Acyl Halides.** Acyl halides, in which the hydroxyl portion of a carboxyl group is replaced by a halogen, are named by placing the name of the corresponding halide after that of the acyl radical. When another group is present that has priority for citation as principal group or when the acyl halide is attached to a side chain, the prefix haloformyl- is used as, for example, in fluoroformyl-.

**1.1.3.4 Alcohols and Phenols.** The hydroxyl group is indicated by a suffix -ol when it is the principal group attached to the parent compound and by the prefix hydroxy- when another group with higher priority for citation is present or when the hydroxy group is present in a side chain. When confusion may arise in employing the suffix -ol, the hydroxy group is indicated as a prefix; this terminology is also used when the hydroxyl group is attached to a heterocycle, as, for example, in the name 3-hydroxythiophene to avoid confusion with thiophenol ( $\text{C}_6\text{H}_5\text{SH}$ ). Designations such as isopropanol, *sec*-butanol, and *tert*-butanol are incorrect because no hydrocarbon exists to which the suffix can be added. Many trivial names are retained. These structures are shown in Table 1.10. The radicals ( $\text{RO}-$ ) are named by adding -oxy as a suffix to the name of the R radical, e.g., pentyloxy for  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{O}-$ . These contractions are exceptions: methoxy ( $\text{CH}_3\text{O}-$ ), ethoxy ( $\text{C}_2\text{H}_5\text{O}-$ ), propoxy ( $\text{C}_3\text{H}_7\text{O}-$ ), butoxy ( $\text{C}_4\text{H}_9\text{O}-$ ), and phenoxy ( $\text{C}_6\text{H}_5\text{O}-$ ). For unsubstituted radicals only, one may use isopropoxy [ $(\text{CH}_3)_2\text{CH}-\text{O}-$ ], isobutoxy [ $(\text{CH}_3)_2\text{CH}_2\text{CH}-\text{O}-$ ], *sec*-butoxy [ $\text{CH}_3\text{CH}_2\text{CH}(\text{CH}_3)-\text{O}-$ ], and *tert*-butoxy [ $(\text{CH}_3)_3\text{C}-\text{O}-$ ].

**TABLE 1.10** Retained Trivial Names of Alcohols and Phenols with Structures

|                            |                                                                                                                                                                                                                          |

1,3,5-TrihydroxybenzenePicric acid  
2,4,6-TrinitrophenolStyphnic acid  
1,3-Dihydroxy-2,4,6-trinitrobenzene

Bivalent radicals of the form  $\text{O}-\text{Y}-\text{O}$  are named by adding -dioxy to the name of the bivalent radicals except when forming part of a ring system. Examples are  $-\text{O}-\text{CH}_2-\text{O}-$  (methylenedioxy),  $-\text{O}-\text{CO}-\text{O}-$  (carbonyldioxy), and  $-\text{O}-\text{SO}_2-\text{O}-$  (sulfonyldioxy). Anions derived from alcohols or phenols are named by changing the final -ol to -olate.

Salts composed of an anion,  $\text{RO}-$ , and a cation, usually a metal, can be named by citing first the cation and then the  $\text{RO}$  anion (with its ending changed to -yl oxide), e.g., sodium benzyl oxide for  $\text{C}_6\text{H}_5\text{CH}_2\text{ONa}$ . However, when the radical has an abbreviated name, such as methoxy, the ending -oxy is changed to -oxide. For example,  $\text{CH}_3\text{ONa}$  is named sodium methoxide (not sodium methylate).

**1.1.3.5 Aldehydes.** When the group  $-\text{C}(=\text{O})\text{H}$ , usually written  $-\text{CHO}$ , is attached to carbon at one (or both) end(s) of a linear acyclic chain the name is formed by adding the suffix -al (or -dial) to the name of the hydrocarbon containing the same number of carbon atoms. Examples are butanal for  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CHO}$  and propanedial for,  $\text{OHCCH}_2\text{CHO}$ .

Naming an acyclic polyaldehyde can be handled in two ways. First, when more than two aldehyde groups are attached to an unbranched chain, the proper affix is added to -carbaldehyde, which becomes the suffix to the name of the longest chain carrying the maximum number of aldehyde groups. The name and numbering of the main chain do not include the carbon atoms of the aldehyde groups. Second, the name is formed by adding the prefix formyl- to the name of the -dial that incorporates the principal chain. Any other chains carrying aldehyde groups are named by the use of formylalkyl- prefixes. Examples are

When the aldehyde group is directly attached to a carbon atom of a ring system, the suffix -carbaldehyde is added to the name of the ring system, e.g., 2-naphthalenecarbaldehyde. When the aldehyde group is separated from the ring by a chain of carbon atoms, the compound is named (1) as a derivative of the acyclic system or (2) by conjunctive nomenclature, for example, (1) (2-naphthyl)propionaldehyde or (2) 2-naphthalenepropionaldehyde.

An aldehyde group is denoted by the prefix formyl- when it is attached to a nitrogen atom in a ring system or when a group having priority for citation as principal group is present and part of a cyclic system.

When the corresponding monobasic acid has a trivial name, the name of the aldehyde may be formed by changing the ending -ic acid or -oic acid to -aldehyde. Examples are

|                 |                              |
|-----------------|------------------------------|
| Formaldehyde    | Acrylaldehyde (not acrolein) |
| Acetaldehyde    | Benzaldehyde                 |
| Propionaldehyde | Cinnamaldehyde               |
| Butyraldehyde   | 2-Furaldehyde (not furfural) |

The same is true for polybasic acids, with the proviso that all the carboxyl groups must be changed to aldehyde; then it is not necessary to introduce affixes. Examples are

Glyceraldehyde

Succinaldehyde

Glycolaldehyde

Phthalaldehyde (*o*-, *m*-, *p*-)

Malonaldehyde

These trivial names may be retained: citral (3,7-dimethyl-2,6-octadienal), vanillin (4-hydroxy-3-methoxybenzaldehyde), and piperonal (3,4-methylenedioxybenzaldehyde).

**1.1.3.6 Amides.** For primary amides the suffix -amide is added to the systematic name of the parent acid. For example,  $\text{CH}_3\text{—CO—NH}_2$  is acetamide. Oxamide is retained for  $\text{H}_2\text{N—CO—CO—NH}_2$ . The name -carboxylic acid is replaced by -carboxamide.

For amino acids having trivial names ending in -ine, the suffix -amide is added after the name of the acid (with elision of *e* for monoamides). For example,  $\text{H}_2\text{N—CH}_2\text{—CO—NH}_2$  is glycine-amide.

In naming the radical  $\text{R—CO—NH—}$ , either (1) the -yl ending of  $\text{RCO—}$  is changed to -amido or (2) the radicals are named as acylamino radicals. For example,

The latter nomenclature is always used for amino acids with trivial names.

*N*-substituted primary amides are named either (1) by citing the substituents as *N* prefixes or (2) by naming the acyl group as an *N* substituent of the parent compound. For example,

**1.1.3.7 Amines.** Amines are preferably named by adding the suffix -amine (and any multiplying affix) to the name of the parent radical. Examples are

Locants of substituents of symmetrically substituted derivatives of symmetrical amines are distinguished by primes or else the names of the complete substituted radicals are enclosed in parentheses. Unsymmetrically substituted derivatives are named similarly or as *N*-substituted products of a primary amine (after choosing the most senior of the radicals to be the parent amine). For example,

Complex cyclic compounds may be named by adding the suffix -amine or the prefix amino- (or aminoalkyl-) to the name of the parent compound. Thus three names are permissible for

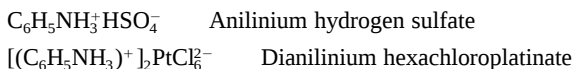

Complex linear polyamines are best designated by replacement nomenclature. These trivial names are retained: aniline, benzidine, phenetidine, toluidine, and xylydine.

The bivalent radical  $\text{—NH—}$  linked to two identical radicals can be denoted by the prefix imino-, as well as when it forms a bridge between two carbon ring atoms. A trivalent nitrogen atom linked to three identical radicals is denoted by the prefix nitrilo-. Thus ethylenediaminetetraacetic acid (an allowed exception) should be named ethylenedinitrilotetraacetic acid.

**1.1.3.8 Ammonium Compounds.** Salts and hydroxides containing quadricovalent nitrogen are named as a substituted ammonium salt or hydroxide. The names of the substituting radicals precede the word *ammonium*, and then the name of the anion is added as a separate word. For example,  $(\text{CH}_3)_4\text{N}^+\text{I}^-$  is tetramethylammonium iodide.

When the compound can be considered as derived from a base whose name does not end in -amine, its quaternary nature is denoted by adding ium to the name of that base (with elision of *e*), substituent groups are cited as prefixes, and the name of the anion is added separately at the end. Examples are

The names *choline* and *betaine* are retained for unsubstituted compounds.

In complex cases, the prefixes amino- and imino- may be changed to ammonio- and iminio- and are followed by the name of the molecule representing the most complex group attached to this nitrogen atom and are preceded by the names of the other radicals attached to this nitrogen. Finally the name of the anion is added separately. For example, the name might be 1-trimethylammonio-acridine chloride or 1-acridinyltrimethylammonium chloride.

When the preceding rules lead to inconvenient names, then (1) the unaltered name of the base may be used followed by the name of the anion or (2) for salts of hydrohalogen acids only the unaltered name of the base is used followed by the name of the hydrohalide. An example of the latter would be 2-ethyl-*p*-phenylenediamine monohydrochloride.

**1.1.3.9 Azo Compounds.** When the azo group ( $\text{—N=N—}$ ) connects radicals derived from identical unsubstituted molecules, the name is formed by adding the prefix azo- to the name of the parent unsubstituted molecules. Substituents are denoted by prefixes and suffixes. The azo group has priority for lowest-numbered locant. Examples are azobenzene for  $\text{C}_6\text{H}_5\text{—N=N—C}_6\text{H}_5$ , azobenzene-4-sulfonic acid for  $\text{C}_6\text{H}_5\text{—N=N—C}_6\text{H}_4\text{SO}_3\text{H}$ , and 2',4-dichloroazobenzene-4'-sulfonic acid for  $\text{ClC}_6\text{H}_4\text{—N=N—C}_6\text{H}_3\text{ClSO}_3\text{H}$ .

When the parent molecules connected by the azo group are different, azo is placed between the complete names of the parent molecules, substituted or unsubstituted. Locants are placed between the affix azo and the names of the molecules to which each refers. Preference is given to the more complex parent molecule for citation as the first component, e.g., 2-aminonaphthalene-1-azo-(4'-chloro-2'-methylbenzene).

In an alternative method, the senior component is regarded as substituted by  $\text{RN=N—}$ , this group R being named as a radical. Thus 2-(7-phenylazo-2-naphthylazo)anthracene is the name by this alternative method for the compound named anthracene-2-azo-2'-naphthalene-7'-azobenzene.

**1.1.3.10 Azoxy Compounds.** Where the position of the azoxy oxygen atom is unknown or immaterial, the compound is named in accordance with azo rules, with the affix azo replaced by azoxy. When the position of the azoxy oxygen atom in an unsymmetrical compound is designated, a prefix *NNO-* or *ONN-* is used. When both the groups attached to the azoxy radical are cited in the name of the compound, the prefix *NNO-* specifies that the second of these two groups is attached directly

to  $\text{—N(O)—}$ ; the prefix *ONN-* specifies that the first of these two groups is attached directly to  $\text{—N(O)—}$ . When only one parent compound is cited in the name, the prefixed *ONN-* and *NNO-* specify that the group carrying the primed and unprimed substituents is connected, respectively, to the  $\text{—N(O)—}$  group. The prefix *NON-* signifies that the position of the oxygen atom is unknown; the azoxy group is then written as  $\text{—N}_2\text{O—}$ . For example,

2,2',4-Trichloro-*NNO*-azoxybenzene

**1.1.3.11 Boron Compounds.** Molecular hydrides of boron are called boranes. They are named by using a multiplying affix to designate the number of boron atoms and adding an Arabic numeral within parentheses as a suffix to denote the number of hydrogen atoms present. Examples are pentaborane(9) for  $\text{B}_5\text{H}_9$  and pentaborane(11) for  $\text{B}_5\text{H}_{11}$ .

Organic ring systems are named by replacement nomenclature. Three- to ten-membered monocyclic ring systems containing uncharged boron atoms may be named by the specialist nomenclature for heterocyclic systems. Organic derivatives are named as outlined for substitutive nomenclature. The complexity of boron nomenclature precludes additional details; the text by Rigaudy and Klesney should be consulted.

**1.1.3.12 Carboxylic Acids.** Carboxylic acids may be named in several ways. First,  $\text{—COOH}$  groups replacing  $\text{CH}_3\text{—}$  at the end of the main chain of an acyclic hydrocarbon are denoted by adding -oic acid to the name of the hydrocarbon. Second, when the  $\text{—COOH}$  group is the principal group, the suffix -carboxylic acid can be added to the name of the parent chain whose name and chain numbering *does not include* the carbon atom of the  $\text{—COOH}$  group. The former nomenclature is preferred unless use of the ending -carboxylic acid leads to citation of a larger number of carboxyl groups as suffix. Third, carboxyl groups are designated by the prefix carboxy- when attached to a group named as a substituent or when another group is present that has higher priority for citation as principal group. In all cases, the principal chain should be linked to as many carboxyl groups as possible even though it might not be the longest chain present. Examples are

(1) Heptanoic acid

(2) 1-Hexanecarboxylic acid

(2) Cyclohexanecarboxylic acid

(3) 2-(Carboxymethyl)-1,4-hexanedicarboxylic acid

Removal of the OH from the  $\text{—COOH}$  group to form the acyl radical results in changing the ending -oic acid to -oyl or the ending -carboxylic acid to -carbonyl. Thus the radical  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CO—}$  is named either pentanoyl or butanecarbonyl. When the hydroxyl has not been removed from all carboxyl groups present in an acid, the remaining carboxyl groups are denoted by the prefix carboxy-. For example,  $\text{HOOCCH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CO—}$  is named 6-carboxyhexanoyl.

**TABLE 1.11** Names of Some Carboxylic Acids

| Systematic name               | Trivial name | Systematic name                                   | Trivial name   |
|-------------------------------|--------------|---------------------------------------------------|----------------|
| Methanoic                     | Formic       | <i>trans</i> -Methylbutenedioic                   | Mesaconic*     |
| Ethanoic                      | Acetic       |                                                   |                |
| Propanoic                     | Propionic    | 1,2,2-Trimethyl-1,3-cyclopentanedicarboxylic acid | Camphoric      |
| Butanoic                      | Butyric      |                                                   |                |
| 2-Methylpropanoic             | Isobutyric*  |                                                   |                |
| Pentanoic                     | Valeric      | Benzenecarboxylic                                 | Benzoic        |
| 3-Methylbutanoic              | Isovaleric*  | 1,2-Benzenedicarboxylic                           | Phthalic       |
| 2,2-Dimethylpropanoic         | Pivalic*     | 1,3-Benzenedicarboxylic                           | Isophthalic    |
| Hexanoic                      | (Caproic)    | 1,4-Benzenedicarboxylic                           | Terephthalic   |
| Heptanoic                     | (Enanthic)   | Naphthalenecarboxylic                             | Naphthoic      |
| Octanoic                      | (Caprylic)   | Methylbenzenecarboxylic                           | Toluic         |
| Decanoic                      | (Capric)     | 2-Phenylpropanoic                                 | Hydratropic    |
| Dodecanoic                    | Lauric*      | 2-Phenylpropenoic                                 | Atropic        |
| Tetradecanoic                 | Myristic*    | <i>trans</i> -3-Phenylpropenoic                   | Cinnamic       |
| Hexadecanoic                  | Palmitic*    | Furancarboxylic                                   | Furoic         |
| Octadecanoic                  | Stearic*     | Thiophenecarboxylic                               | Thenoic        |
|                               |              | 3-Pyridinecarboxylic                              | Nicotinic      |
|                               |              | 4-Pyridinecarboxylic                              | Isonicotinic   |
| Ethanedioic                   | Oxalic       |                                                   |                |
| Propanedioic                  | Malonic      | Hydroxyethanoic                                   | Glycolic       |
| Butanedioic                   | Succinic     | 2-Hydroxypropanoic                                | Lactic         |
| Pentanedioic                  | Glutaric     | 2,3-Dihydroxypropanoic                            | Glyceric       |
| Hexanedioic                   | Adipic       | Hydroxypropanedioic                               | Tartronic      |
| Heptanedioic                  | Pimelic*     | Hydroxybutanedioic                                | Malic          |
| Octanedioic                   | Suberic*     | 2,3-Dihydroxybutanedioic                          | Tartaric       |
| Nonanedioic                   | Azelaic*     | 3-Hydroxy-2-phenylpropanoic                       | Tropic         |
| Decanedioic                   | Sebacic*     | 2-Hydroxy-2,2-diphenyl-ethanoic                   | Benzilic       |
| Propenoic                     | Acrylic      | 2-Hydroxybenzoic                                  | Salicylic      |
| Propynoic                     | Propiolic    | Methoxybenzoic                                    | Anisic         |
| 2-Methylpropenoic             | Methacrylic  | 4-Hydroxy-3-methoxybenzoic                        | Vanillic       |
| <i>trans</i> -2-Butenoic      | Crotonic     |                                                   |                |
| <i>cis</i> -2-Butenoic        | Isocrotonic  | 3,4-Dimethoxybenzoic                              | Veratric       |
| <i>cis</i> -9-Octadecenoic    | Oleic        | 3,4-Methylenedioxybenzoic                         | Piperonylic    |
| <i>trans</i> -9-Octadecenoic  | Elaidic      | 3,4-Dihydroxybenzoic                              | Protocatechuic |
| <i>cis</i> -Butenedioic       | Maleic       | 3,4,5-Trihydroxybenzoic                           | Gallic         |
| <i>trans</i> -Butenedioic     | Fumaric      |                                                   |                |
| <i>cis</i> -Methylbutenedioic | Citraconic*  |                                                   |                |

\* Systematic names should be used in derivatives formed by substitution on a carbon atom.

**Note:** The names in parentheses are abandoned but are listed for reference to older literature.

Many trivial names exist for acids; these are listed in Table 1.11. Generally, radicals are formed by replacing -ic acid by -oyl.\* When a trivial name is given to an acyclic monoacid or diacid, the numeral 1 is always given as locant to the carbon atom of a carboxyl group in the acid or to the carbon atom with a free valence in the radical RCO—.

\* Exceptions: formyl, acetyl, propionyl, butyryl, isobutyryl, valeryl, isovaleryl, oxalyl, malonyl, succinyl, glutaryl, furoyl, and thenoyl.

**1.1.3.13 Ethers ( $R^1-O-R^2$ ).** In substitutive nomenclature, one of the possible radicals,  $R-O-$ , is stated as the prefix to the parent compound that is senior from among  $R^1$  or  $R^2$ . Examples are methoxyethane for  $CH_3OCH_2CH_3$  and butoxyethanol for  $C_4H_9OCH_2CH_2OH$ .

When another principal group has precedence and oxygen is linking two identical parent compounds, the prefix oxy- may be used, as with 2,2'-oxydiethanol for  $HOCH_2CH_2OCH_2CH_2OH$ .

Compounds of the type  $RO-Y-OR$ , where the two parent compounds are identical and contain a group having priority over ethers for citation as suffix, are named as assemblies of identical units. For example,  $HOOC-CH_2-O-CH_2CH_2-O-CH_2-COOH$  is named 2,2'-(ethylene-dioxy)diacetic acid.

Linear polyethers derived from three or more molecules of aliphatic dihydroxy compounds, particularly when the chain length exceeds ten units, are most conveniently named by open-chain replacement nomenclature. For example,  $CH_3CH_2-O-CH_2CH_2-O-CH_2CH_3$  could be 3,6-dioxaoctane or (2-ethoxy)ethoxyethane.

An oxygen atom directly attached to two carbon atoms already forming part of a ring system or to two carbon atoms of a chain may be indicated by the prefix epoxy-. For example,  $CH_2-CH-O-CH_2Cl$  is named 1-chloro-2,3-epoxypropane.

Symmetrical linear polyethers may be named (1) in terms of the central oxygen atom when there is an odd number of ether oxygen atoms or (2) in terms of the central hydrocarbon group when there is an even number of ether oxygen atoms. For example,  $C_2H_5-O-C_4H_9-O-C_4H_9-O-C_2H_5$  is bis-(4-ethoxybutyl)ether, and 3,6-dioxaoctane (earlier example) could be named 1,2-bis-(ethoxy)ethane.

Partial ethers of polyhydroxy compounds may be named (1) by substitutive nomenclature or (2) by stating the name of the polyhydroxy compound followed by the name of the etherifying radical(s) followed by the word *ether*. For example,

Cyclic ethers are named either as heterocyclic compounds or by specialist rules of heterocyclic nomenclature. Radicofunctional names are formed by citing the names of the radicals  $R^1$  and  $R^2$  followed by the word *ether*. Thus methoxyethane becomes ethyl methyl ether and ethoxyethane becomes diethyl ether.

**1.1.3.14 Halogen Derivatives.** Using substitutive nomenclature, names are formed by adding prefixes listed in Table 1.8 to the name of the parent compound. The prefix perhalo- implies the replacement of all hydrogen atoms by the particular halogen atoms.

Cations of the type  $R^1R^2X^+$  are given names derived from the halonium ion,  $H_2X^+$ , by substitution, e.g., diethyliodonium chloride for  $(C_2H_5)_2I^+Cl^-$ .

Retained are these trivial names; bromoform ( $CHBr_3$ ), chloroform ( $CHCl_3$ ), fluoroform ( $CHF_3$ ), iodoform ( $CHI_3$ ), phosgene ( $COCl_2$ ), thiophosgene ( $CSCl_2$ ), and dichlorocarbene radical ( $\triangleright CCl_2$ ). Inorganic nomenclature leads to such names as carbonyl and thiocarbonyl halides ( $COX_2$  and  $CSX_2$ ) and carbon tetrahalides ( $CX_4$ ).

**1.1.3.15 Hydroxylamines and Oximes.** For  $RNH-OH$  compounds, prefix the name of the radical  $R$  to hydroxylamine. If another substituent has priority as principal group, attach the prefix

hydroxyamino- to the parent name. For example,  $\text{C}_6\text{H}_5\text{NHOH}$  would be named *N*-phenylhydroxylamine, but  $\text{HOC}_6\text{H}_4\text{NHOH}$  would be (hydroxyamino)phenol, with the point of attachment indicated by a locant preceding the parentheses.

Compounds of the type  $\text{R}^1\text{NH—OR}^2$  are named (1) as alkoxyamino derivatives of compound  $\text{R}^1\text{H}$ , (2) as *N,O*-substituted hydroxylamines, (3) as alkoxyamines (even if  $\text{R}^1$  is hydrogen), or (4) by the prefix aminooxy- when another substituent has priority for parent name. Examples of each type are

1. 2-(Methoxyamino)-8-naphthalenecarboxylic acid for  $\text{CH}_3\text{ONH—C}_{10}\text{H}_6\text{COOH}$
2. *O*-Phenylhydroxylamine for  $\text{H}_2\text{N—O—C}_6\text{H}_5$  or *N*-phenylhydroxylamine for  $\text{C}_6\text{H}_5\text{NH—OH}$
3. Phenoxyamine for  $\text{H}_2\text{N—O—C}_6\text{H}_5$  (not preferred to *O*-phenylhydroxylamine)
4. Ethyl (aminooxy)acetate for  $\text{H}_2\text{N—O—CH}_2\text{CO—OC}_2\text{H}_5$

Acyl derivatives,  $\text{RCO—NH—OH}$  and  $\text{H}_2\text{N—O—CO—R}$ , are named as *N*-hydroxy derivatives of amides and as *O*-acylhydroxylamines, respectively. The former may also be named as hydroxamic acids. Examples are *N*-hydroxyacetamide for  $\text{CH}_3\text{CO—NH—OH}$  and *O*-acetylhydroxylamine for  $\text{H}_2\text{N—O—CO—CH}_3$ . Further substituents are denoted by prefixes with *O*- and/or *N*-locants. For example,  $\text{C}_6\text{H}_5\text{NH—O—C}_2\text{H}_5$  would be *O*-ethyl-*N*-phenylhydroxylamine or *N*-ethoxylaniline.

For oximes, the word *oxime* is placed after the name of the aldehyde or ketone. If the carbonyl group is not the principal group, use the prefix hydroxyimino-. Compounds with the group  $\text{>N—OR}$  are named by a prefix alkoxyimino- as oxime *O*-ethers or as *O*-substituted oximes. Compounds with the group  $\text{>C=N(O)R}$  are named by adding *N*-oxide after the name of the alkylideneaminc compound. For amine oxides, add the word *oxide* after the name of the base, with locants. For example,  $\text{C}_5\text{H}_5\text{N—O}$  is named pyridine *N*-oxide or pyridine 1-oxide.

**1.1.3.16 Imines.** The group  $\text{>C=NH}$  is named either by the suffix -imine or by citing the name of the bivalent radical  $\text{R}^1\text{R}^2\text{C}<$  as a prefix to amine. For example,  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH=NH}$  could be named 1-butanimine or butylideneamine. When the nitrogen is substituted, as in  $\text{CH}_2=\text{N—CH}_2\text{CH}_3$ , the name is *N*-(methylidene)ethylamine.

Quinones are exceptions. When one or more atoms of quinonoid oxygen have been replaced by  $\text{>NH}$  or  $\text{>NR}$ , they are named by using the name of the quinone followed by the word *imine* (and preceded by proper affixes). Substituents on the nitrogen atom are named as prefixes. Examples are

**1.1.3.17 Ketenes.** Derivatives of the compound ketene,  $\text{CH}_2=\text{C=O}$ , are named by substitutive nomenclature. For example,  $\text{C}_4\text{H}_9\text{CH=C=O}$  is butyl ketene. An acyl derivative, such as  $\text{CH}_3\text{CH}_2\text{—CO—CH}_2\text{CH=C=O}$ , may be named as a polyketone, 1-hexene-1,4-dione. Bisketene is used for two to avoid ambiguity with diketene (dimeric ketene).

**1.1.3.18 Ketones.** Acyclic ketones are named (1) by adding the suffix -one to the name of the hydrocarbon forming the principal chain or (2) by citing the names of the radicals  $\text{R}^1$  and  $\text{R}^2$  followed

by the word *ketone*. In addition to the preceding nomenclature, acyclic monoacyl derivatives of cyclic compounds may be named (3) by prefixing the name of the acyl group to the name of the cyclic compound. For example, the three possible names of

- (1) 1-(2-Furyl)-1-propanone
- (2) Ethyl 2-furyl ketone
- (3) 2-Propionylfuran

When the cyclic component is benzene or naphthalene, the -ic acid or -oic acid of the acid corresponding to the acyl group is changed to -ophenone or -onaphthone, respectively. For example,  $\text{C}_6\text{H}_5\text{—CO—CH}_2\text{CH}_2\text{CH}_3$  can be named either butyrophenone (or butanophenone) or phenyl propyl ketone.

Radicalofunctional nomenclature can be used when a carbonyl group is attached directly to carbon atoms in two ring systems and no other substituent is present having priority for citation.

When the methylene group in polycarbocyclic and heterocyclic ketones is replaced by a keto group, the change may be denoted by attaching the suffix -one to the name of the ring system. However, when  $\geq\text{CH}$  in an unsaturated or aromatic system is replaced by a keto group, two alternative names become possible. First, the maximum number of noncumulative double bonds is added after introduction of the carbonyl group(s), and any hydrogen that remains to be added is denoted as indicated hydrogen with the carbonyl group having priority over the indicated hydrogen for lower-numbered locant. Second, the prefix oxo- is used, with the hydrogenation indicated by hydro prefixes; hydrogenation is considered to have occurred before the introduction of the carbonyl group. For example,

- (1) 1-(2H)-Naphthalenone
- (2) 1-Oxo-1,2-dihydronaphthalene

When another group having higher priority for citation as principal group is also present, the ketonic oxygen may be expressed by the prefix oxo-, or one can use the name of the carbonyl-containing radical, as, for example, acyl radicals and oxo-substituted radicals. Examples are

4-(4'-Oxohexyl)-1-benzoic acid

1,2,4-Triacetylbenzene

Diketones and tetraketones derived from aromatic compounds by conversion of two or four  $\geq\text{CH}$  groups into keto groups, with any necessary rearrangement of double bonds to a quinonoid structure, are named by adding the suffix -quinone and any necessary affixes.

Polyketones in which two or more contiguous carbonyl groups have rings attached at each end

may be named (1) by the radicofunctional method or (2) by substitutive nomenclature. For example,

- (1) 2-Naphthyl 2-pyridyl diketone  
(2) 1-(2-Naphthyl)-2-(2-pyridyl)ethanedione

Some trivial names are retained: acetone (2-propanone), biacetyl (2,3-butanedione), propiophenone ( $\text{C}_6\text{H}_5-\text{CO}-\text{CH}_2\text{CH}_3$ ), chalcone ( $\text{C}_6\text{H}_5-\text{CH}=\text{CH}-\text{CO}-\text{C}_6\text{H}_5$ ), and deoxybenzoin ( $\text{C}_6\text{H}_5-\text{CH}_2-\text{CO}-\text{C}_6\text{H}_5$ ).

These contracted names of heterocyclic nitrogen compounds are retained as alternatives for systematic names, sometimes with indicated hydrogen. In addition, names of oxo derivatives of fully saturated nitrogen heterocycles that systematically end in -idinone are often contracted to end in -idone when no ambiguity might result. For example,

2-Pyridone  
2(1H)-Pyridone

4-Pyridone  
4(1H)-Pyridone

2-Quinolone  
2(1H)-Quinolone

4-Quinolone  
4(1H)-Quinolone

1-Isoquinolone  
1(2H)-Isoquinolone

4-Oxazolone  
4(5H)-Oxazolone

4-Pyrazolone  
4(5H)-Pyrazolone

5-Pyrazolone  
5(4H)-Pyrazolone

4-Isioxazoline  
4(5H)-Isioxazoline

4-Thiazolone  
4(5H)-Thiazolone

9-Acrindone  
9(10H)-Acrindone

**1.1.3.19 Lactones, Lactides, Lactams, and Lactims.** When the hydroxy acid from which water may be considered to have been eliminated has a trivial name, the lactone is designated by substituting -olactone for -ic acid. Locants for a carbonyl group are numbered as low as possible, even before that of a hydroxyl group.

Lactones formed from aliphatic acids are named by adding -olide to the name of the nonhydroxylated hydrocarbon with the same number of carbon atoms. The suffix -olide signifies the change of  $\text{>CH}\cdots\text{CH}_3$  into  $\text{>C}\cdots\text{C=O}$ .

Structures in which one or more (but not all) rings of an aggregate are lactone rings are named by placing -carbolactone (denoting the  $\text{—O—CO—}$  bridge) after the names of the structures that

remain when each bridge is replaced by two hydrogen atoms. The locant for  $\text{—CO—}$  is cited before that for the ester oxygen atom. An additional carbon atom is incorporated into this structure as compared to the -olide.

These trivial names are permitted:  $\gamma$ -butyrolactone,  $\gamma$ -valerolactone, and  $\delta$ -valerolactone. Names based on heterocycles may be used for all lactones. Thus,  $\gamma$ -butyrolactone is also tetrahydro-2-furanone or dihydro-2(3H)-furanone.

*Lactides*, intermolecular cyclic esters, are named as heterocycles. *Lactams* and *lactims*, containing a  $\text{—CO—NH—}$  and  $\text{—C(OH)=N—}$  group, respectively, are named as heterocycles, but they may also be named with -lactam or -lactim in place of -olide. For example,

**1.1.3.20 Nitriles and Related Compounds.** For acids whose systematic names end in -carboxylic acid, nitriles are named by adding the suffix -carbonitrile when the  $\text{—CN}$  group replaces the  $\text{—COOH}$  group. The carbon atom of the  $\text{—CN}$  group is excluded from the numbering of a chain to which it is attached. However, when the triple-bonded nitrogen atom is considered to replace three hydrogen atoms at the end of the main chain of an acyclic hydrocarbon, the suffix -nitrile is added to the name of the hydrocarbon. Numbering begins with the carbon attached to the nitrogen. For example,  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CN}$  is named (1) pentanecarbonitrile or (2) hexanenitrile.

Trivial acid names are formed by changing the endings -oic acid or -ic acid to -onitrile. For example,  $\text{CH}_3\text{CN}$  is acetonitrile. When the  $\text{—CN}$  group is not the highest priority group, the  $\text{—CN}$  group is denoted by the prefix cyano-.

In order of decreasing priority for citation of a functional class name, and the prefix for substitutive nomenclature, are the following related compounds:

| Functional group | Prefix            | Radicofunctional ending |
|------------------|-------------------|-------------------------|
| $\text{—NC}$     | Isocyano-         | Isocyanide              |
| $\text{—OCN}$    | Cyanato-          | Cyanate                 |
| $\text{—NCO}$    | Isocyanato-       | Isocyanate              |
| $\text{—ONC}$    | —                 | Fulminate               |
| $\text{—SCN}$    | Thiocyanato-      | Thiocyanate             |
| $\text{—NCS}$    | Isothiocyanato-   | Isothiocyanate          |
| $\text{—SeCN}$   | Selenocyanato-    | Selenocyanate           |
| $\text{—NCSe}$   | Isoselenocyanato- | Isoselenocyanate        |

**1.1.3.21 Peroxides.** Compounds of the type  $\text{R—O—OH}$  are named (1) by placing the name of the radical R before the word *hydroperoxide* or (2) by use of the prefix *hydroperoxy-* when another parent name has higher priority. For example,  $\text{C}_2\text{H}_5\text{OOH}$  is ethyl hydroperoxide.

Compounds of the type  $\text{R}^1\text{O—OR}^2$  are named (1) by placing the names of the radicals in alphabetical order before the word *peroxide* when the group  $\text{—O—O—}$  links two chains, two rings, or a ring and a chain, (2) by use of the affix *dioxy* to denote the bivalent group  $\text{—O—O—}$  for naming assemblies of identical units or to form part of a prefix, or (3) by use of the prefix *epidioxy-* when the peroxide group forms a bridge between two carbon atoms, a ring, or a ring system.

Examples are methyl propyl peroxide for  $\text{CH}_3\text{—O—O—C}_3\text{H}_7$  and 2,2'-dioxydiacetic acid for  $\text{HOOC—CH}_2\text{—O—O—CH}_2\text{—COOH}$ .

**1.1.3.22 Phosphorus Compounds.** Acyclic phosphorus compounds containing only one phosphorus atom, as well as compounds in which only a single phosphorus atom is in each of several functional groups, are named as derivatives of the parent structures listed in Table 1.12. Often these

**TABLE 1.12** Parent Structures of Phosphorus-Containing Compounds

| Formula                                                                                                                                                                                                                              | Parent name                                                                                                                                               | Substitutive prefix                                                                                                                                                                                                                                   | Radicofunctional ending                                                |

are purely hypothetical parent structures. When hydrogen attached to phosphorus is replaced by a hydrocarbon group, the derivative is named by substitution nomenclature. When hydrogen of an  $\text{—OH}$  group is replaced, the derivative is named by radicofunctional nomenclature. For example,  $\text{C}_2\text{H}_5\text{PH}_2$  is ethylphosphine;  $(\text{C}_2\text{H}_5)_2\text{PH}$ , diethylphosphine;  $\text{CH}_3\text{P}(\text{OH})_2$ , dihydroxy-methyl-phosphine or methylphosphonous acid;  $\text{C}_2\text{H}_5\text{—PO}(\text{Cl})(\text{OH})$ , ethylchlorophosphonic acid or ethylphosphonochloridic acid or hydrogen chlorodioxoethylphosphate(V);  $\text{CH}_3\text{CH}(\text{PH}_2)\text{COOH}$ , 2-phosphinopropionic acid;  $\text{HP}(\text{CH}_2\text{COOH})_2$ , phosphinediylacetic acid;  $(\text{CH}_3)\text{HP}(\text{O})\text{OH}$ , methylphosphinic acid or hydrogen hydridomethyl dioxophosphate(V);  $(\text{CH}_3\text{O})_3\text{PO}$ , trimethyl phosphate; and  $(\text{CH}_3\text{O})_3\text{P}$ , trimethyl phosphite.

**1.1.3.23 Salts and Esters of Acids.** Neutral salts of acids are named by citing the cation(s) and then the anion, whose ending is changed from -oic to -oate or from -ic to -ate. When different acidic residues are present in one structure, prefixes are formed by changing the anion ending -ate to -ato- or -ide to -ido-. The prefix carboxylato- denotes the ionic group  $\text{—COO}^-$ . The phrase (metal) salt of (the acid) is permissible when the carboxyl groups are not all named as affixes.

Acid salts include the word *hydrogen* (with affixes, if appropriate) inserted between the name of the cation and the name of the anion (or word *salt*).

Esters are named similarly, with the name of the alkyl or aryl radical replacing the name of the

cation. Acid esters of acids and their salts are named as neutral esters, but the components are cited in the order: cation, alkyl or aryl radical, hydrogen, and anion. Locants are added if necessary. For example,

Ester groups in  $\text{R}^1\text{—CO—OR}^2$  compounds are named (1) by the prefix alkoxycarbonyl- or aryloxy carbonyl- for  $\text{—CO—OR}^2$  when the radical  $\text{R}^1$  contains a substituent with priority for citation as principal group or (2) by the prefix acyloxy- for  $\text{R}^1\text{—CO—O—}$  when the radical  $\text{R}^2$  contains a substituent with priority for citation as principal group. Examples are

Methyl 3-methoxycarbonyl-2-naphthalenebutyrate

The trivial name *acetox*y is retained for the  $\text{CH}_3\text{—CO—O—}$  group. Compounds of the type  $\text{R}^2\text{C(OR}^3)_3$  are named as  $\text{R}^2$  esters of the hypothetical ortho acids. For example,  $\text{CH}_3\text{C(OCH}_3)_3$  is trimethyl orthoacetate.

**1.1.3.24 Silicon Compounds.**  $\text{SiH}_4$  is called silane; its acyclic homologs are called disilane, trisilane, and so on, according to the number of silicon atoms present. The chain is numbered from one end to the other so as to give the lowest-numbered locant in radicals to the free valence or to substituents on a chain. The abbreviated form silyl is used for the radical  $\text{SiH}_3\text{—}$ . Numbering and citation of side chains proceed according to the principles set forth for hydrocarbon chains. Cyclic nonaromatic structures are designated by the prefix *cyclo-*.

When a chain or ring system is composed entirely of alternating silicon and oxygen atoms, the parent name *siloxane* is used with a multiplying affix to denote the number of silicon atoms present. The parent name *silazane* implies alternating silicon and nitrogen atoms; multiplying affixes denote the number of silicon atoms present.

The prefix *sila-* designates replacement of carbon by silicon in replacement nomenclature. Prefix names for radicals are formed analogously to those for the corresponding carbon-containing compounds. Thus silyl is used for  $\text{SiH}_3\text{—}$ , silylene for  $\text{—SiH}_2\text{—}$ , silylidyne for  $\text{—SiH<}$ , as well as trily, tetrayl, and so on for free valences(s) on ring structures.

#### 1.1.3.25 Sulfur Compounds

**Bivalent Sulfur.** The prefix *thio*, placed before an affix that denotes the oxygen-containing group or an oxygen atom, implies the replacement of that oxygen by sulfur. Thus the suffix *-thiol* denotes  $\text{—SH}$ , *-thione* denotes  $\text{—(C)=S}$  and implies the presence of an  $\text{=S}$  at a nonterminal carbon atom, *-thioic acid* denotes  $[(\text{C})=\text{S}]\text{OH} \rightleftharpoons [(\text{C})=\text{O}]\text{SH}$  (that is, the *O*-substituted acid and the *S*-substi-

tuted acid, respectively), -dithioc acid denotes  $[\text{—C(S)}]\text{SH}$ , and -thial denotes  $\text{—(C)HS}$  (or -carbothialdehyde denotes  $\text{—CHS}$ ). When -carboxylic acid has been used for acids, the sulfur analog is named -carbothioic acid or -carbodithioic acid.

Prefixes for the groups  $\text{HS—}$  and  $\text{RS—}$  are mercapto- and alkylthio-, respectively; this latter name may require parentheses for distinction from the use of thio- for replacement of oxygen in a trivially named acid. Examples of this problem are  $4\text{-C}_2\text{H}_5\text{—C}_6\text{H}_4\text{—CSOH}$  named *p*-ethyl(thio)benzoic acid and  $4\text{-C}_2\text{H}_5\text{—S—C}_6\text{H}_4\text{—COOH}$  named *p*-(ethylthio)benzoic acid. When  $\text{—SH}$  is not the principal group, the prefix mercapto- is placed before the name of the parent compound to denote an unsubstituted  $\text{—SH}$  group.

The prefix thioxo- is used for naming  $\text{=S}$  in a thioketone. Sulfur analogs of acetals are named as alkylthio- or arylthio-. For example,  $\text{CH}_3\text{CH}(\text{SCH}_3)\text{OCH}_3$  is 1-methoxy-1-(methylthio)ethane. Prefix forms for -carbothioic acids are hydroxy(thiocarbonyl)- when referring to the *O*-substituted acid and mercapto(carbonyl)- for the *S*-substituted acid.

Salts are formed as with oxygen-containing compounds. For example,  $\text{C}_2\text{H}_5\text{—S—Na}$  is named either sodium ethanethiolate or sodium ethyl sulfide. If mercapto- has been used as a prefix, the salt is named by use of the prefix sulfido- for  $\text{—S}^-$ .

Compounds of the type  $\text{R}^1\text{—S—R}^2$  are named alkylthio- (or arylthio-) as a prefix to the name of  $\text{R}^1$  or  $\text{R}^2$ , whichever is the senior.

**Sulfonium Compounds.** Sulfonium compounds of the type  $\text{R}^1\text{R}^2\text{R}^3\text{S}^+\text{X}^-$  are named by citing in alphabetical order the radical names followed by -sulfonium and the name of the anion. For heterocyclic compounds, -ium is added to the name of the ring system. Replacement of  $>\text{CH}$  by sulfonium sulfur is denoted by the prefix thionia-, and the name of the anion is added at the end.

**Organosulfur Halides.** When sulfur is directly linked only to an organic radical and to a halogen atom, the radical name is attached to the word *sulfur* and the name(s) and number of the halide(s) are stated as a separate word. Alternatively, the name can be formed from  $\text{R—SOH}$ , a sulfenic acid whose radical prefix is sulfenyl-. For example,  $\text{CH}_3\text{CH}_2\text{—S—Br}$  would be named either ethylsulfur monobromide or ethanesulfenyl bromide. When another principal group is present, a composite prefix is formed from the number and substitutive name(s) of the halogen atoms in front of the syllable thio. For example,  $\text{BrS—COOH}$  is (bromothio)formic acid.

**Sulfoxides.** Sulfoxides,  $\text{R}^1\text{—SO—R}^2$ , are named by placing the names of the radicals in alphabetical order before the word *sulfoxide*. Alternatively, the less senior radical is named followed by sulfinyl- and concluded by the name of the senior group. For example,  $\text{CH}_3\text{CH}_2\text{—SO—CH}_2\text{CH}_2\text{CH}_3$  is named either ethyl propyl sulfoxide or 1-(ethylsulfinyl)propane.

When an  $>\text{SO}$  group is incorporated in a ring, the compound is named an oxide.

**Sulfones.** Sulfones,  $\text{R}^1\text{—SO}_2\text{—R}^2$ , are named in an analogous manner to sulfoxides, using the word *sulfone* in place of *sulfoxide*. In prefixes, the less senior radical is followed by -sulfonyl-. When the  $>\text{SO}_2$  group is incorporated in a ring, the compound is named as a dioxide.

**Sulfur Acids.** Organic oxy acids of sulfur, that is,  $\text{—SO}_3\text{H}$ ,  $\text{—SO}_2\text{H}$ , and  $\text{—SOH}$ , are named sulfonic acid, sulfinic acid, and sulfenic acid, respectively. In subordinate use, the respective prefixes are sulfo-, sulfinio, and sulfeno-. The grouping  $\text{—SO}_2\text{—O—SO}_2\text{—}$  or  $\text{—SO—O—SO—}$  is named sulfonic or sulfinic anhydride, respectively.

Inorganic nomenclature is employed in naming sulfur acids and their derivatives in which sulfur is linked only through oxygen to the organic radical. For example,  $(\text{C}_2\text{H}_5\text{O})_2\text{SO}_2$  is diethyl sulfate and  $\text{C}_2\text{H}_5\text{O—SO}_2\text{—OH}$  is ethyl hydrogen sulfate. Prefixes *O*- and *S*- are used where necessary to denote attachment to oxygen and to sulfur, respectively, in sulfur replacement compounds. For example,  $\text{CH}_3\text{—S—SO}_2\text{—ONa}$  is sodium *S*-methyl thiosulfate.

When sulfur is linked only through nitrogen, or through nitrogen and oxygen, to the organic radical, naming is as follows: (1) *N*-substituted amides are designated as *N*-substituted derivatives of the sulfur amides and (2) compounds of the type  $\text{R—NH—SO}_3\text{H}$  may be named as *N*-substituted

sulfamic acids or by the prefix sulfoamino- to denote the group  $\text{HO}_3\text{S}-\text{NH}-$ . The groups  $-\text{N}=\text{SO}$  and  $-\text{N}=\text{SO}_2$  are named sulfinylamines and sulfonylamines, respectively.

**Sultones and Sultams.** Compounds containing the group  $-\text{SO}_2-\text{O}-$  as part of the ring are called -sultone. The  $-\text{SO}_2-$  group has priority over the  $-\text{O}-$  group for lowest-numbered locant.

Similarly, the  $-\text{SO}_2-\text{N}=\text{}$  group as part of a ring is named by adding -sultam to the name of the hydrocarbon with the same number of carbon atoms. The  $-\text{SO}_2-$  has priority over  $-\text{N}=\text{}$  for lowest-numbered locant.

### 1.1.4 Stereochemistry

Concepts in stereochemistry, that is, chemistry in three-dimensional space, are in the process of rapid expansion. This section will deal with only the main principles. The compounds discussed will be those that have identical molecular formulas but differ in the arrangement of their atoms in space. *Stereoisomers* is the name applied to these compounds.

Stereoisomers can be grouped into three categories: (1) Conformational isomers differ from each other only in the way their atoms are oriented in space, but can be converted into one another by rotation about sigma bonds. (2) Geometric isomers are compounds in which rotation about a double bond is restricted. (3) Configurational isomers differ from one another only in configuration about a chiral center, axis, or plane. In subsequent structural representations, a broken line denotes a bond projecting behind the plane of the paper and a wedge denotes a bond projecting in front of the plane of the paper. A line of normal thickness denotes a bond lying essentially in the plane of the paper.

**1.1.4.1 Conformational Isomers.** A molecule in a conformation into which its atoms return spontaneously after small displacements is termed a *conformer*. Different arrangements of atoms that can be converted into one another by rotation about single bonds are called *conformational isomers* (see Fig. 1.1). A pair of conformational isomers can be but do not have to be mirror images of each other. When they are not mirror images, they are called *diastereomers*.

**FIGURE 1.1** Conformations of ethane.  
(a) Eclipsed; (b) staggered.

**Acyclic Compounds.** Different conformations of acyclic compounds are best viewed by construction of ball-and-stick molecules or by use of Newman projections (see Fig. 1.2). Both types of representations are shown for ethane. Atoms or groups that are attached at opposite ends of a single bond should be viewed along the bond axis. If two atoms or groups attached at opposite ends of the bond appear one directly behind the other, these atoms or groups are described as eclipsed. That portion of the molecule is described as being in the eclipsed conformation. If not eclipsed, the atoms

**FIGURE 1.2** Newman projections for ethane. (a) Staggered; (b) eclipsed.

or groups and the conformation may be described as staggered. Newman projections show these conformations clearly.

Certain physical properties show that rotation about the single bond is not quite free. For ethane there is an energy barrier of about  $3 \text{ kcal} \cdot \text{mol}^{-1}$  ( $12 \text{ kJ} \cdot \text{mol}^{-1}$ ). The potential energy of the molecule is at a minimum for the staggered conformation, increases with rotation, and reaches a maximum at the eclipsed conformation. The energy required to rotate the atoms or groups about the carbon-carbon bond is called *torsional energy*. Torsional strain is the cause of the relative instability of the eclipsed conformation or any intermediate skew conformations.

In butane, with a methyl group replacing one hydrogen on each carbon of ethane, there are several different staggered conformations (see Fig. 1.3). There is the *anti*-conformation in which the methyl groups are as far apart as they can be (dihedral angle of  $180^\circ$ ). There are two *gauche* conformations in which the methyl groups are only  $60^\circ$  apart; these are two nonsuperimposable mirror images of each other. The *anti*-conformation is more stable than the *gauche* by about  $0.9 \text{ kcal} \cdot \text{mol}^{-1}$  ( $4 \text{ kJ} \cdot \text{mol}^{-1}$ ). Both are free of torsional strain. However, in a *gauche* conformation the methyl groups are closer together than the sum of their van der Waals' radii. Under these conditions van der Waals' forces are repulsive and raise the energy of conformation. This strain can affect not only the relative stabilities of various staggered conformations but also the heights of the energy barriers

**FIGURE 1.3** Conformations of butane. (a) *Anti*-staggered; (b) eclipsed; (c) *gauche*-staggered; (d) eclipsed; (e) *gauche*-staggered; (f) eclipsed. (Eclipsed conformations are slightly staggered for convenience in drawing; actually they are superimposed.)

between them. The energy maximum (estimated at  $4.8$  to  $6.1 \text{ kcal} \cdot \text{mol}^{-1}$  or  $20$  to  $25 \text{ kJ} \cdot \text{mol}^{-1}$ ) is reached when two methyl groups swing past each other (the eclipsed conformation) rather than past hydrogen atoms.

**Cyclic Compounds.** Although cyclic aliphatic compounds are often drawn as if they were planar geometric figures (a triangle for cyclopropane, a square for cyclobutane, and so on), their structures are not that simple. Cyclopropane does possess the maximum angle strain if one considers the difference between a tetrahedral angle ( $109.5^\circ$ ) and the  $60^\circ$  angle of the cyclopropane structure. Nevertheless the cyclopropane structure is thermally quite stable. The highest electron density of the carbon-carbon bonds does not lie along the lines connecting the carbon atoms. Bonding electrons lie principally outside the triangular internuclear lines and result in what is known as *bent bonds* (see Fig. 1.4).

Cyclobutane has less angle strain than cyclopropane (only  $19.5^\circ$ ). It is also believed to have some bent-bond character associated with the carbon-carbon bonds. The molecule exists in a nonplanar conformation in order to minimize hydrogen-hydrogen eclipsing strain.

Cyclopentane is nonplanar, with a structure that resembles an envelope (see Fig. 1.5). Four of the carbon atoms are in one plane, and the fifth is out of that plane. The molecule is in continual motion so that the out-of-plane carbon moves rapidly around the ring.

The 12 hydrogen atoms of cyclohexane do not occupy equivalent positions. In the chair conformation six hydrogen atoms are perpendicular to the average plane of the molecule and six are directed outward from the ring, slightly above or below the molecular plane (see Fig. 1.6). Bonds which are perpendicular to the molecular plane are known as *axial bonds*, and those which extend outward

FIGURE 1.4 The bent bonds ("tear drops") of cyclopropane.

FIGURE 1.5 The conformations of cyclopentane.

FIGURE 1.6 The two chair conformations of cyclohexane; *a* = axial hydrogen atom and *e* = equatorial hydrogen atom.

from the ring are known as *equatorial bonds*. The three axial bonds directed upward originate from alternate carbon atoms and are parallel with each other; a similar situation exists for the three axial bonds directed downward. Each equatorial bond is drawn so as to be parallel with the ring carbon-carbon bond once removed from the point of attachment to that equatorial bond. At room temperature, cyclohexane is interconverting rapidly between two chair conformations. As one chair form converts to the other, all the equatorial hydrogen atoms become axial and all the axial hydrogens become equatorial. The interconversion is so rapid that all hydrogen atoms on cyclohexane can be considered equivalent. Interconversion is believed to take place by movement of one side of the chair structure to produce the twist boat, and then movement of the other side of the twist boat to give the other chair form. The chair conformation is the most favored structure for cyclohexane. No angle strain is encountered since all bond angles remain tetrahedral. Torsional strain is minimal because all groups are staggered.

In the boat conformation of cyclohexane (Fig. 1.7) eclipsing torsional strain is significant, although no angle strain is encountered. Nonbonded interaction between the two hydrogen atoms across the ring from each other (the “flagpole” hydrogens) is unfavorable. The boat conformation is about  $6.5 \text{ kcal} \cdot \text{mol}^{-1}$  ( $27 \text{ kJ} \cdot \text{mol}^{-1}$ ) higher in energy than the chair form at  $25^\circ\text{C}$ .

**FIGURE 1.7** The boat conformation of cyclohexane. *a* = axial hydrogen atom and *e* = equatorial hydrogen atom.

**FIGURE 1.8** Twist-boat conformation of cyclohexane.

A modified boat conformation of cyclohexane, known as the twist boat (Fig. 1.8), or skew boat, has been suggested to minimize torsional and nonbonded interactions. This particular conformation is estimated to be about  $1.5 \text{ kcal} \cdot \text{mol}^{-1}$  ( $6 \text{ kJ} \cdot \text{mol}^{-1}$ ) lower in energy than the boat form at room temperature.

The medium-size rings (7 to 12 ring atoms) are relatively free of angle strain and can easily take a variety of spatial arrangements. They are not large enough to avoid all nonbonded interactions between atoms.

Disubstituted cyclohexanes can exist as *cis-trans* isomers as well as axial-equatorial conformers. Two isomers are predicted for 1,4-dimethylcyclohexane (see Fig. 1.9). For the *trans* isomer the diequatorial conformer is the energetically favorable form. Only one *cis* isomer is observed, since the two conformers of the *cis* compound are identical. Interconversion takes place between the conformational (equatorial-axial) isomers but not configurational (*cis-trans*) isomers.

**FIGURE 1.9** Two isomers of 1,4-dimethylcyclohexane. (a) *Trans* isomer; (b) *cis* isomer.

**FIGURE 1.10** Two isomers of decahydronaphthalene, or bicyclo[4.4.0]decane. (a) *Trans* isomer; (b) *cis* isomer.

The bicyclic compound decahydronaphthalene, or bicyclo[4.4.0]decane, has two fused six-membered rings. It exists in *cis* and *trans* forms (see Fig. 1.10), as determined by the configurations at the bridgehead carbon atoms. Both *cis*- and *trans*-decahydronaphthalene can be constructed with two chair conformations.

**1.1.4.2 Geometrical Isomerism.** Rotation about a carbon-carbon double bond is restricted because of interaction between the *p* orbitals which make up the pi bond. Isomerism due to such restricted rotation about a bond is known as *geometric isomerism*. Parallel overlap of the *p* orbitals of each carbon atom of the double bond forms the molecular orbital of the pi bond. The relatively large barrier to rotation about the pi bond is estimated to be nearly  $63 \text{ kcal} \cdot \text{mol}^{-1}$  ( $263 \text{ kJ} \cdot \text{mol}^{-1}$ ).

When two different substituents are attached to each carbon atom of the double bond, *cis-trans* isomers can exist. In the case of *cis*-2-butene (Fig. 1.11a), both methyl groups are on the same side of the double bond. The other isomer has the methyl groups on opposite sides and is designated as *trans*-2-butene (Fig. 1.11b). Their physical properties are quite different. Geometric isomerism can also exist in ring systems; examples were cited in the previous discussion on conformational isomers.

For compounds containing only double-bonded atoms, the reference plane contains the double-bonded atoms and is perpendicular to the plane containing these atoms and those directly attached to them. It is customary to draw the formulas so that the reference plane is perpendicular to that of

**FIGURE 1.11** Two isomers of 2-butene. (a) *Cis* isomer, bp 3.8°C, mp −138.9°C, dipole moment 0.33 D; (b) *trans* isomer, bp 0.88°C, mp −105.6°C, dipole moment 0 D.

the paper. For cyclic compounds the reference plane is that in which the ring skeleton lies or to which it approximates. Cyclic structures are commonly drawn with the ring atoms in the plane of the paper.

**1.1.4.3 Sequence Rules for Geometric Isomers and Chiral Compounds.** Although *cis* and *trans* designations have been used for many years, this approach becomes useless in complex systems. To eliminate confusion when each carbon of a double bond or a chiral center is connected to different groups, the Cahn, Ingold, and Prelog system for designating configuration about a double bond or a chiral center has been adopted by IUPAC. Groups on each carbon atom of the double bond are assigned a first (1) or second (2) priority. Priority is then compared at one carbon relative to the other. When both first priority groups are on the *same side* of the double bond, the configuration is designated as *Z* (from the German *zusammen*, “together”), which was formerly *cis*. If the first priority groups are on *opposite sides* of the double bond, the designation is *E* (from the German *entgegen*, “in opposition to”), which was formerly *trans*. (See Fig. 1.12.)

**FIGURE 1.12** Configurations designated by priority groups. (a) *Z* (*cis*); (b) *E* (*trans*).

When a molecule contains more than one double bond, each *E* or *Z* prefix has associated with it the lower-numbered locant of the double bond concerned. Thus (see also the rules that follow)

When the sequence rules permit alternatives, preference for lower-numbered locants and for inclusion in the principal chain is allotted as follows in the order stated: *Z* over *E* groups and *cis* over *trans* cyclic groups. If a choice is still not attained, then the lower-numbered locant for such a preferred

group at the first point of difference is the determining factor. For example,

**Rule 1.** Priority is assigned to atoms on the basis of atomic number. Higher priority is assigned to atoms of higher atomic number. If two atoms are isotopes of the same element, the atom of higher mass number has the higher priority. For example, in 2-butene, the carbon atom of each methyl group receives first priority over the hydrogen atom connected to the same carbon atom. Around the asymmetric carbon atom in chloriodomethanesulfonic acid, the priority sequence is I, Cl, S, H. In 1-bromo-1-deuteroethane, the priority sequence is Cl, C, D, H.

**Rule 2.** When atoms attached directly to a double-bonded carbon have the same priority, the second atoms are considered and so on, if necessary, working outward once again from the double bond or chiral center. For example, in 1-chloro-2-methylbutene, in  $\text{CH}_3$  the second atoms are H, H, H and in  $\text{CH}_2\text{CH}_3$  they are C, H, H. Since carbon has a higher atomic number than hydrogen, the ethyl group has the next highest priority after the chlorine atom.

**Rule 3.** When groups under consideration have double or triple bonds, the multiple-bonded atom is replaced conceptually by two or three single bonds to that same kind of atom.

Thus,  $=\text{A}$  is considered to be equivalent to two A's, or  $\begin{smallmatrix} \text{A} \\ < \\ \text{A} \end{smallmatrix}$  and  $\equiv\text{A}$  equals  $\begin{smallmatrix} \text{A} & & \text{A} \\ < & & < \\ \text{A} & & \text{A} \end{smallmatrix}$ . However, a real  $\begin{smallmatrix} \text{A} \\ < \\ \text{A} \end{smallmatrix}$  has priority over  $=\text{A}$ ; likewise a real  $\begin{smallmatrix} \text{A} & & \text{A} \\ < & & < \\ \text{A} & & \text{A} \end{smallmatrix}$  has priority over  $\equiv\text{A}$ . Actually, both atoms of

a multiple bond are duplicated, or triplicated, so that  $\text{C}=\text{O}$  is treated as  $\begin{smallmatrix} \text{C}-\text{O} \\ | \quad | \\ \text{O} \quad \text{C} \end{smallmatrix}$ , that

is  $\begin{smallmatrix} \text{C}-\text{O} \\ | \\ \text{O} \end{smallmatrix}$  and  $\begin{smallmatrix} \text{O}-\text{C} \\ | \\ \text{C} \end{smallmatrix}$ , and  $\text{C}\equiv\text{N}$  is treated as  $\begin{smallmatrix} \text{C} & & \text{N} \\ / \quad & \backslash & / \\ (\text{N}) & (\text{N}) & (\text{C}) & (\text{N}) \end{smallmatrix}$ . A phenyl carbon

becomes  $\begin{smallmatrix} \text{CH} \\ | \\ -\text{C} & & \text{C} \\ | \quad \backslash \\ \text{CH} \end{smallmatrix}$ . Only the double-bonded atoms themselves are duplicated, not the atoms or

groups attached to them. The duplicated atoms (or phantom atoms) may be considered as carrying atomic number zero. For example, among the groups OH, CHO,  $\text{CH}_2\text{OH}$ , and H, the OH group has the highest priority, and the C(O, O, H) of CHO takes priority over the C(O, H, H) of  $\text{CH}_2\text{OH}$ .

**1.1.4.4 Chirality and Optical Activity.** A compound is chiral (the term *dissymmetric* was formerly used) if it is not superimposable on its mirror image. A chiral compound does not have a plane of symmetry. Each chiral compound possesses one (or more) of three types of chiral element, namely, a chiral center, a chiral axis, or a chiral plane.

**Chiral Center.** The chiral center, which is the chiral element most commonly met, is exemplified by an asymmetric carbon with a tetrahedral arrangement of ligands about the carbon. The ligands comprise four different atoms or groups. One “ligand” may be a lone pair of electrons; another, a phantom atom of atomic number zero. This situation is encountered in sulfoxides or with a nitrogen atom. Lactic acid is an example of a molecule with an asymmetric (chiral) carbon. (See Fig. 1.13b.)

**FIGURE 1.13** Asymmetric (chiral) carbon in the lactic acid molecule.

A simpler representation of molecules containing asymmetric carbon atoms is the Fischer projection, which is shown here for the same lactic acid configurations. A Fischer projection involves

drawing a cross and attaching to the four ends the four groups that are attached to the asymmetric carbon atom. The asymmetric carbon atom is understood to be located where the lines cross. The horizontal lines are understood to represent bonds coming toward the viewer out of the plane of the paper. The vertical lines represent bonds going away from the viewer behind the plane of the paper as if the vertical line were the side of a circle. The principal chain is depicted in the vertical direction; the lowest-numbered (locant) chain member is placed at the top position. These formulas may be moved sideways or rotated through  $180^\circ$  in the plane of the paper, but they may not be removed from the plane of the paper (i.e., rotated through  $90^\circ$ ). In the latter orientation it is essential to use thickened lines (for bonds coming toward the viewer) and dashed lines (for bonds receding from the viewer) to avoid confusion.

**Enantiomers.** Two nonsuperimposable structures that are mirror images of each other are known as *enantiomers*. Enantiomers are related to each other in the same way that a right hand is related to a left hand. Except for the direction in which they rotate the plane of polarized light, enantiomers are identical in all physical properties. Enantiomers have identical chemical properties except in their reactivity toward optically active reagents.

Enantiomers rotate the plane of polarized light in opposite directions but with equal magnitude. If the light is rotated in a clockwise direction, the sample is said to be dextrorotatory and is designed as (+). When a sample rotates the plane of polarized light in a counterclockwise direction, it is said to be levorotatory and is designed as (–). Use of the designations *d* and *l* is discouraged.

**Specific Rotation.** Optical rotation is caused by individual molecules of the optically active compound. The amount of rotation depends upon how many molecules the light beam encounters in passing through the tube. When allowances are made for the length of the tube that contains the sample and the sample concentration, it is found that the amount of rotation, as well as its direction, is a characteristic of each individual optically active compound.

Specific rotation is the number of degrees of rotation observed if a 1-dm tube is used and the compound being examined is present to the extent of 1 g per 100 mL. The density for a pure liquid replaces the solution concentration.

$$\text{Specific rotation} = [\alpha] = \frac{\text{observed rotation (degrees)}}{\text{length (dm)} \times (\text{g}/100 \text{ mL})}$$

The temperature of the measurement is indicated by a superscript and the wavelength of the light employed by a subscript written after the bracket; for example,  $[\alpha]_{590}^{20}$  implies that the measurement was made at 20°C using 590-nm radiation.

**Optically Inactive Chiral Compounds.** Although chirality is a necessary prerequisite for optical activity, chiral compounds are not necessarily optically active. With an equal mixture of two enantiomers, no net optical rotation is observed. Such a mixture of enantiomers is said to be *racemic* and is designated as ( $\pm$ ) and not as *dl*. Racemic mixtures usually have melting points higher than the melting point of either pure enantiomer.

A second type of optically inactive chiral compounds, *meso* compounds, will be discussed in the next section.

**Multiple Chiral Centers.** The number of stereoisomers increases rapidly with an increase in the number of chiral centers in a molecule. A molecule possessing two chiral atoms should have four optical isomers, that is, four structures consisting of two pairs of enantiomers. However, if a compound has two chiral centers but both centers have the same four substituents attached, the total number of isomers is three rather than four. One isomer of such a compound is not chiral because it is identical with its mirror image; it has an internal mirror plane. This is an example of a diastereomer. The achiral structure is denoted as a *meso* compound. Diastereomers have different physical and chemical properties from the optically active enantiomers. Recognition of a plane of symmetry is usually the easiest way to detect a *meso* compound. The stereoisomers of tartaric acid are examples of compounds with multiple chiral centers (see Fig. 1.14), and one of its isomers is a *meso* compound.

FIGURE 1.14 Isomers of tartaric acid.

When the asymmetric carbon atoms in a chiral compound are part of a ring, the isomerism is more complex than in acyclic compounds. A cyclic compound which has two different asymmetric carbons with different sets of substituent groups attached has a total of  $2^2 = 4$  optical isomers: an enantiomeric pair of *cis* isomers and an enantiomeric pair of *trans* isomers. However, when the two asymmetric centers have the same set of substituent groups attached, the *cis* isomer is a *meso* compound and only the *trans* isomer is chiral. (See Fig. 1.15.)

**Torsional Asymmetry.** Rotation about single bonds of most acyclic compounds is relatively free at ordinary temperatures. There are, however, some examples of compounds in which nonbonded

**FIGURE 1.15** Isomers of cyclopropane-1,2-dicarboxylic acid. (a) *Trans* isomer; (b) *meso* isomer.

interactions between large substituent groups inhibit free rotation about a sigma bond. In some cases these compounds can be separated into pairs of enantiomers.

A *chiral axis* is present in chiral biaryl derivatives. When bulky groups are located at the *ortho* positions of each aromatic ring in biphenyl, free rotation about the single bond connecting the two rings is inhibited because of torsional strain associated with twisting rotation about the central single bond. Interconversion of enantiomers is prevented (see Fig. 1.16).

For compounds possessing a chiral axis, the structure can be regarded as an elongated tetrahedron to be viewed along the axis. In deciding upon the absolute configuration it does not matter from which end it is viewed; the nearer pair of ligands receives the first two positions in the order of precedence (see Fig. 1.17). For the meaning of (*S*), see the discussion under Absolute Configuration on p. 1.49.

A *chiral plane* is exemplified by the plane containing the benzene ring and the bromine and oxygen atoms in the chiral compound shown in Fig. 1.18. Rotation of the benzene ring around the oxygen-to-ring single bonds is inhibited when  $x$  is small (although no critical size can be reasonably established).

**FIGURE 1.16** Isomers of biphenyl compounds with bulky groups attached at the *ortho* positions.

**FIGURE 1.17** Example of a chiral axis.

**FIGURE 1.18** Example of a chiral plane.

**FIGURE 1.19** Viewing angle as a means of designating the absolute configuration of compounds with a chiral axis. (a) (*R*)-2-Butanol (sequence clockwise); (b) (*S*)-2-butanol (sequence counterclockwise).

**Absolute Configuration.** The terms absolute stereochemistry and absolute configuration are used to describe the three-dimensional arrangement of substituents around a chiral element. A general system for designating absolute configuration is based upon the priority system and sequence rules. Each group attached to a chiral center is assigned a number, with number one the highest-priority group. For example, the groups attached to the chiral center of 2-butanol (see Fig. 1.19) are assigned these priorities: 1 for OH, 2 for CH<sub>2</sub>CH<sub>3</sub>, 3 for CH<sub>3</sub>, and 4 for H. The molecule is then viewed from the side opposite the group of lowest priority (the hydrogen atom), and the arrangement of the remaining groups is noted. If, in proceeding from the group of highest priority to the group of second priority and thence to the third, the eye travels in a clockwise direction, the configuration is specified *R* (from the Latin *rectus*, “right”); if the eye travels in a counterclockwise direction, the configuration is specified *S* (from the Latin *sinister*, “left”). The complete name includes both configuration and direction of optical rotation, as for example, (*S*)-(+)-2-butanol.

The relative configurations around the chiral centers of many compounds have been established. One optically active compound is converted to another by a sequence of chemical reactions which are stereospecific; that is, each reaction is known to proceed spatially in a specific way. The configuration of one chiral compound can then be related to the configuration of the next in sequence. In order to establish absolute configuration, one must carry out sufficient stereospecific reactions to relate a new compound to another of known absolute configuration. Historically the configuration of **D**-(+)-2,3-dihydroxypropanal has served as the standard to which all configuration has been compared. The absolute configuration assigned to this compound has been confirmed by an X-ray crystallographic technique.

### 1.1.5 Chemical Abstracts Indexing System

When compounds of complex structure are considered, the number of name possibilities grows rapidly. To avoid having index entries for all possible names, Chemical Abstracts Service has developed what might be called the principle of inversion. The indexing system employs inverted

entries to bring together related compounds in an alphabetically arranged index. The *index heading parent* from the Chemical Substance Index appears in the Formula Index in lightface before the “comma of inversion.” The *substituents* follow the “comma of inversion” in alphabetical order. Any *name modification* appears on a separate line. If necessary, the chemical description is completed by citation of an associated ion, a functional derivative, a “salt with” or “compound with” term, and/or a stereochemical descriptor.

Quite naturally there is a certain amount of arbitrariness in this system, although the IUPAC nomenclature is followed. The preferred *Chemical Abstracts* index names for chemical substances have been, with very few exceptions, continued unchanged (since 1972) as set forth in the *Ninth Collective Index Guide* and in a journal article.\* Any revisions appear in the updated *Index Guide*; new editions appear at 18-month intervals. Appendix VI is of particular interest to chemists. Reprints of the Appendix may be purchased from Chemical Abstracts Service, Marketing Division, P.O. Box 3012, Columbus, Ohio 43210.

**TABLE 1.15** Physical Constants of Organic Compounds

See also the special tables of polymers, rubbers, fats, oils, and waxes.

*Names* of the compounds in the table starting on p. 1.76 are arranged alphabetically. Usually substitutive nomenclature is employed; exceptions generally involve ethers, sulfides, sulfones, and sulfoxides. Each compound is given a number within its letter classification; thus compound c209 is 3-chlorophenol. Section 1.1, Nomenclature of Organic Compounds, should be consulted to familiarize oneself with present nomenclature systems.

*Synonyms or Alternate Names* are found at the bottom of each spread in their alphabetical listing; the number following the same refers to the numerical place of this compound in the table. For example, epichlorohydrin, c120, indicates that this compound is found listed under the name 1-chloro-2,3-epoxypropane.

*Formulas* are presented in semistructural form when no ambiguity is possible. Complicated systems are drawn in complete structural form and located at the bottom of each page and keyed to the number of the entry.

*Beilstein Reference.* In this column is found the reference to the volume and page numbers of the fourth edition of Beilstein, *Handbuch der Organischen Chemie* (Springer-Verlag, New York, 1918). Thus the entry 9, 202 refers to an entry in volume 9 appearing on page 202. When the volume number has a superscript attached, reference is made to the appropriate supplementary volume. For example, 12<sup>2</sup>, 404 indicates that the compound will be found listed in the second supplement to volume 12 on page 404. The earliest Beilstein entry is listed. Supplementary information may be found in the supplements to the basic series; such coordinating references (series number, volume number, and page number of the main edition) along with the system number are found at the top of each *odd-numbered page*. Similarly, a back reference such as H93; E II 64; E III 190 in a volume of Supplementary Series IV means that previous items on this compound are found in the same volume of the

| 1. Base SI units          |                 |                    |                                                                                                                                                                                                                                                                                    |
| Amount of substance       | mole            | mol                | Amount of substance which contains as many specified entities as there are atoms of carbon-12 in exactly 0.012 kg of that nuclide. The elementary entities must be specified and may be atoms, molecules, ions, electrons, other particles, or specified groups of such particles. |
| Electric current          | ampere          | A                  | Magnitude of the current that, when flowing through each of two straight parallel conductors of infinite length, of negligible cross-section, separated by 1 meter in a vacuum, results in a force between the two wires of $2 \times 10^{-7}$ newton per meter of length.         |
| Length                    | meter           | m                  | Distance light travels in a vacuum during 1/299 792 458 of a second.                                                                                                                                                                                                               |
| Luminous intensity        | candela         | cd                 | Luminous intensity, in a given direction, of a source that emits monochromatic radiation of frequency $540 \times 10^{12}$ hertz and that has a radiant intensity in that direction of 1/683 watt per steradian.                                                                   |
| Mass                      | kilogram        | kg                 | Mass of a cylinder of platinum-iridium alloy kept at Paris.                                                                                                                                                                                                                        |
| Temperature               | kelvin          | K                  | Defined as the fraction 1/273.16 of the thermodynamic temperature of the triple point of water.                                                                                                                                                                                    |
| Time                      | second          | s                  | Duration of 9 192 631 770 periods of the radiation corresponding to the transition between the two hyperfine levels of the ground state of the cesium-133 atom.                                                                                                                    |
| 2. Supplementary SI units |                 |                    |                                                                                                                                                                                                                                                                                    |
| Plane angle               | radian          | rad                | The plane angle between two radii of a circle which cut off on the circumference an arc equal in length to the radius.                                                                                                                                                             |
| Solid angle               | steradian       | sr                 | The solid angle which, having its vertex in the center of a sphere, cuts off an area of the surface of the sphere equal to that of a square with sides of length equal to the radius of the sphere.                                                                                |

TABLE 2.1 Fundamental Physical Constants (Continued)

<sup>2</sup> The ångström and bar are approved for temporary use with SI units; however, they should not be introduced if not used at present.

<sup>3</sup> The name dalton and symbol Da have not been approved although they are often used for large molecules.

TABLE 2.2 Physical and Chemical Symbols and Definitions

Symbols separated by commas represent equivalent recommendations. Symbols for physical and chemical quantities should be printed in *italic* type. Subscripts and superscripts which are themselves symbols for physical quantities should be italicized; all others should be in Roman type. Vectors and matrices should be printed in boldface italic type, e.g., ***B***, ***b***. Symbols for units should be printed in Roman type and should remain unaltered in the plural, and should not be followed by a full stop except at the end of a sentence. | Electromotive force                                | $E$                            | V                   | $E = \int (F/Q) \, ds$                            |
| Impedance                                          | $Z$                            | $\Omega$            | $Z = R + iX$                                      |
| Loss angle <sup>f</sup>                            | $\delta$                       | rad                 | $\delta = (\pi/2) + \phi_I - \phi_U$              |
| Magnetic dipole moment                             | $\mathbf{m}, \boldsymbol{\mu}$ | $A \cdot m^2$       | $E_p = -\mathbf{mB}$                              |
| Magnetic field strength                            | $\mathbf{H}$                   | $A \cdot m^{-1}$    | $\mathbf{B} = \mu \mathbf{H}$                     |
| Magnetic flux                                      | $\Phi$                         | Wb                  | $\Phi = \int \mathbf{B} \, dA$                    |
| Magnetization (magnetic dipole moment per volume)  | $\mathbf{M}$                   | $A \cdot m^{-1}$    | $\mathbf{M} = (\mathbf{B}/\mu_0) - \mathbf{H}$    |
| Magnetic susceptibility                            | $\chi, \kappa$                 |                     | $\chi = \mu_r - 1$                                |
| Magnetic vector potential                          | $\mathbf{A}$                   | $Wb \cdot m^{-1}$   | $\mathbf{B} = \nabla \mathbf{A}$                  |
| Molar magnetic susceptibility                      | $\chi_m$                       | $m^3/mol$           | $\chi_m = V_m \chi$                               |
| Mutual inductance                                  | $M, L_{12}$                    | H                   | $E_1 = L_{12}(dI_2/dt)$                           |
| Permeability                                       | $\mu$                          | $H \cdot m^{-1}$    | $\mathbf{B} = \mu \mathbf{H}$                     |
| Permeability of vacuum                             | $\mu_0$                        | $H \cdot m^{-1}$    |                                                   |
| Permittivity                                       | $\epsilon$                     | $F \cdot m^{-1}$    | $\mathbf{D} = \epsilon \mathbf{E}$                |
| Permittivity of vacuum                             | $\epsilon_0$                   | $F \cdot m^{-1}$    | $\epsilon_0 = \mu_0^{-1} c_0^{-2}$                |
| Poynting vector                                    | $\mathbf{S}$                   | $W \cdot m^{-2}$    | $\mathbf{S} = \mathbf{E} \cdot \mathbf{H}$        |
| Quantity of electricity, electric charge           | $Q$                            | C                   |                                                   |
| Reactance                                          | $X$                            | $\Omega$            | $X = (U/I) \sin \delta$                           |
| Relative permeability                              | $\mu_r$                        |                     | $\mu_r = \mu/\mu_0$                               |
| Relative permittivity <sup>g</sup>                 | $\epsilon_r$                   |                     | $\epsilon_r = \epsilon/\epsilon_0$                |
| Resistivity                                        | $\rho$                         | $\Omega \cdot m$    | $\rho = E/j$                                      |
| Self-inductance                                    | $L$                            | H                   | $E = -L(dI/dt)$                                   |
| Susceptance                                        | $B$                            | S                   | $Y = G + iB$                                      |

<sup>f</sup>  $\phi_I$  and  $\phi_U$  are the phases of current and potential difference.

<sup>g</sup> This quantity was formerly called the dielectric constant.

| Second virial coefficient                | $B$              | $m^3 \cdot mol^{-1}$                  | $pV_m = RT(1 + B/V_m + \cdots)$               |
| Specific quantity $X$                    | $x$              | (varies)                              | $x = X/m$                                     |
| Standard chemical potential              | $\mu^0$          | $J \cdot mol^{-1}$                    |                                               |
| Standard partial molar enthalpy          | $H^0$            | $J \cdot mol^{-1}$                    | $H^0 = \mu^0 + TS$                            |
| Standard partial molar entropy           | $S^0$            | $J \cdot mol^{-1} \cdot K^{-1}$       | $S^0 = -(\partial \mu^0 / \partial T)$        |
| Standard reaction enthalpy               | $\Delta_r H^0$   | $J \cdot mol^{-1}$                    | $\Delta_r H^0 = \sum \nu H^0$                 |
| Standard reaction entropy                | $\Delta_r S^0$   | $J \cdot mol^{-1} \cdot K^{-1}$       | $\Delta_r S^0 = \sum \nu S^0$                 |
| Standard reaction Gibbs energy           | $\Delta_r G^0$   | $J \cdot mol^{-1}$                    | $\Delta_r G^0 = \sum \nu \mu^0$               |
| Surface tension                          | $\gamma, \sigma$ | $J \cdot m^{-2},$<br>$N \cdot m^{-1}$ | $\gamma = (\partial G / \partial A_s)_{T,p}$  |
| Thermodynamic temperature                | $T$              | K                                     |                                               |
| Work                                     | $w, W$           | J                                     |                                               |

Symbols used as subscripts to denote a chemical reaction or process:

|     |                                   |     |                               |
|-----|-----------------------------------|-----|-------------------------------|
| ads | adsorption                        | mix | mixing of fluids              |
| at  | atomization                       | r   | reaction in general           |
| c   | combustion reaction               | sol | solution of solute in solvent |
| dil | dilution of a solution            | sub | sublimation (solid to gas)    |
| f   | formation reaction                | trs | transition (two phases)       |
| fus | melting, fusion (solid to liquid) |     |                               |

Recommended superscripts:

|    |                                     |          |                   |
|----|-------------------------------------|----------|-------------------|
| +  | activated complex, transition state | $\infty$ | infinite solution |
| E  | excess quantity                     | *        | pure substance    |
| id | ideal                               | °        | standard          |

N. Transport properties

| Name                         | Symbol       | SI unit                       | Definition                |
|------------------------------|--------------|-------------------------------|---------------------------|
| Coefficient of heat transfer | $h, (k, K)$  | $W \cdot m^{-2} \cdot K^{-1}$ | $h = J_q / \Delta T$      |
| Diffusion coefficient        | $D$          | $m^2 \cdot s^{-1}$            | $D = J_n / (dc/dl)$       |
| Flux (of a quantity $X$ )    | $J_X, J$     | (varies)                      | $J_X = A^{-1} dX/dt$      |
| Heat flow rate               | $\phi$       | W                             | $\phi = dq/dt$            |
| Heat flux                    | $J_q$        | $W \cdot m^{-2}$              | $J_q = \phi/A$            |
| Mass flow rate               | $q_m, m$     | $kg \cdot s^{-1}$             | $q_m = dm/dt$             |

**TABLE 2.3** Mathematical Symbols and Abbreviations

| Symbol or abbreviation          | Meaning                                                 |
|---------------------------------|---------------------------------------------------------|
| +                               | Plus                                                    |
| −                               | Minus                                                   |
| ±                               | Plus or minus                                           |
| ∓                               | Minus or plus                                           |
| ≡                               | Identically equal to                                    |
| $\times$ , center dot           | Multiplied by ( $ab$ , $a \times b$ , $a \cdot b$ )     |
| ÷                               | Divided by ( $a/b$ , $ab^{-1}$ )                        |
| ≠                               | Not equal to                                            |
| ≈                               | Approximately equal to                                  |
| ≍                               | Asymptotically equal to                                 |
| >                               | Greater than                                            |
| <                               | Less than                                               |
| ≫                               | Much greater than                                       |
| ≪                               | Much less than                                          |
| ≥                               | Greater than or equal to                                |
| ≤                               | Less than or equal to                                   |
| $\propto$ , ~                   | Proportional to                                         |
| →                               | Tends to, approaches                                    |
| ∞                               | Infinity                                                |
| $a$                             | Magnitude of $a$                                        |
| $a^n$                           | $n$ th power of $a$                                     |
| $\sqrt[n]{a}$ , $a^{1/n}$       | $n$ th root of $a$                                      |
| $\sqrt{a}$ , $a^{1/2}$          | Square root of $a$                                      |
| $\langle a \rangle$ , $\bar{a}$ | Mean value of $a$                                       |
| $\prod_{i=1}^n a_i$ , $\Pi a_i$ | Product of $a_i$                                        |
| $\log a$ or $\log_{10} a$       | Common (or Briggsian) logarithm to the base 10 of $a$   |
| $\log_a b$                      | Logarithm to the base $a$ of $b$                        |
| $\ln b$ , $\log_e b$            | Natural (Napierian) logarithm (to the base $e$ ) of $b$ |
| $e$                             | Base (2.718) of natural system of logarithms            |
| $\pi$                           | Pi (3.1416)                                             |
| $i$                             | Imaginary quantity, square root of minus one            |
| $n!$                            | $n$ factorial ( $n! = 1 \cdot 2 \cdot 3 \cdots n$ )     |
| ∠                               | Angle                                                   |
| ⊥                               | Perpendicular to                                        |
|                                 | Parallel to                                             |
| $a^\circ$                       | $a$ degrees (angle)                                     |
| $a'$                            | $a$ minutes (angle); $a$ prime                          |
| $a''$                           | $a$ seconds (angle); $a$ double prime                   |
| $\sin a$                        | sine of $a$                                             |
| $\cos a$                        | cosine of $a$                                           |
| $\tan a$                        | tangent of $a$                                          |
| $\cot a$                        | cotangent of $a$                                        |
| $\sec a$                        | secant of $a$                                           |
| $\csc a$                        | cosecant of $a$                                         |
| $\arcsin a$ , $\sin^{-1} a$     | Inverse sine of $a$ (angle whose sine is $a$ )          |
| $\arccos a$ , $\cos^{-1} a$     | Inverse cosine of $a$ (angle whose cosine is $a$ )      |
| $\arctan a$ , $\tan^{-1} a$     | Inverse tangent of $a$ (angle whose tangent is $a$ )    |
| $\sinh a$                       | Hyperbolic sine of $a$                                  |
| $\cosh a$                       | Hyperbolic cosine of $a$                                |
| $\tanh a$                       | Hyperbolic tangent of $a$                               |

**TABLE 2.3** Mathematical Symbols and Abbreviations (*Continued*)

| Symbol or abbreviation                       | Meaning                                                      |
|----------------------------------------------|--------------------------------------------------------------|
| $\coth a$                                    | Hyperbolic cotangent of $a$                                  |
| $P(x, y)$                                    | Rectangular coordinate of point $P$                          |
| $P(r, \theta)$                               | Polar coordinate of point $P$                                |
| $f(x), F(x)$                                 | Function of $x$                                              |
| $\Delta x$                                   | Increment of $x$                                             |
| $dy$                                         | Total differential of $y$                                    |
| $\frac{dy}{dx}$ or $f'(x)$                   | Derivative of $y = f(x)$ with respect to $x$                 |
| $\frac{d^2y}{dx^2}$ or $f''(x)$              | Second derivative of $y = f(x)$ with respect to $x$          |
| $\frac{\partial z}{\partial x}$              | Partial derivative of $z$ with respect to $x$                |
| $\frac{\partial^2 z}{\partial x \partial y}$ | Second partial derivative of $z$ with respect to $x$ and $y$ |
| $\int$                                       | Integral of                                                  |
| $\int_a^b$                                   | Integral between the limits $a$ and $b$                      |
| $\lim_{x \rightarrow a} f(x)$                | limit of $f(x)$ as $x$ tends to $a$                          |
| $\sum_{i=1}^n$                               | Summation of $a_i$ between the limits 1 and $n$              |

**TABLE 2.4** SI Prefixes

| Submultiple | Prefix | Symbol | Multiple  | Prefix | Symbol |

| 18                               | octadeca          | 38     | octatriaconta  | 130    | triacontahecta  |

\* In the case of complex entities such as organic ligands (particularly if they are substituted) the multiplying prefixes bis-, tris-, tetrakis-, pentakis-, . . . are used, i.e., -kis is added starting from tetra-. The modified entity is often placed within parentheses to avoid ambiguity.

TABLE 2.5 Greek Alphabet

| Capital   | Lower case | Name    | Capital  | Lower case | Name    |
|-----------|------------|---------|----------|------------|---------|
| A         | $\alpha$   | Alpha   | N        | $\nu$      | Nu      |
| B         | $\beta$    | Beta    | $\Xi$    | $\xi$      | Xi      |
| $\Gamma$  | $\gamma$   | Gamma   | O        | $o$        | Omicron |
| $\Delta$  | $\delta$   | Delta   | $\Pi$    | $\pi$      | Pi      |
| E         | $\epsilon$ | Epsilon | P        | $\rho$     | Rho     |
| Z         | $\zeta$    | Zeta    | $\Sigma$ | $\sigma$   | Sigma   |
| H         | $\eta$     | Eta     | T        | $\tau$     | Tau     |
| $\Theta$  | $\theta$   | Theta   | Y        | $\upsilon$ | Upsilon |
| I         | $\iota$    | Iota    | $\Phi$   | $\phi$     | Phi     |
| K         | $\kappa$   | Kappa   | X        | $\chi$     | Chi     |
| $\Lambda$ | $\lambda$  | Lambda  | $\Psi$   | $\psi$     | Psi     |
| M         | $\mu$      | Mu      | $\Omega$ | $\omega$   | Omega   |

TABLE 2.6 Abbreviations and Standard Letter Symbols

|                                                   |                    |                                       |                            |

**TABLE 2.7** Conversion Factors

The data were compiled by L. P. Busetth for the 13th edition; some entries have been added or modified in view of recent data and SI units.

Relations which are exact are indicated by an asterisk (\*). Factors in parentheses are also exact. Other factors are within  $\pm 5$  in the last significant figure.

**TABLE 2.8** Temperature Conversion Table

The column of figures in bold and which is headed “Reading in °F. or °C. to be converted” refers to the temperature either in degrees Fahrenheit or Celsius which it is desired to convert into the other scale. If converting from Fahrenheit degrees to Celsius degrees, the equivalent temperature will be found in the column headed “°C.”; while if converting from degrees Celsius to degrees Fahrenheit, the equivalent temperature will be found in the column headed “°F.” This arrangement is very similar to that of Sauveur and Boylston, copyrighted 1920, and is published with their permission.

### 2.1.1 Conversion of Thermometer Scales

The following abbreviations are used: °F, degrees Fahrenheit; °C, degrees Celsius; °K, degrees Kelvin; °Ré, degrees Reaumur; °R, degrees Rankine; °Z, degrees on any scale; (fp)“Z”, the freezing point of water on the Z scale; and (bp)“Z”, the boiling point of water on the Z scale. Reference: Dodds, *Chemical and Metallurgical Engineering* **38**:476 (1931).

$$\frac{^{\circ}\text{F} - 32}{180} = \frac{^{\circ}\text{C}}{100} = \frac{^{\circ}\text{Ré}}{80} = \frac{\text{K} - 273}{100} = \frac{^{\circ}\text{R} - 492}{180} = \frac{^{\circ}\text{Z} - (\text{fp})\text{“Z”}}{(\text{bp})\text{“Z”} - (\text{fp})\text{“Z”}}$$

*Examples*

(1) To find the Fahrenheit temperature corresponding to  $-20^{\circ}\text{C}$ :

$$\frac{^{\circ}\text{F} - 32}{180} = \frac{^{\circ}\text{C}}{100} \quad \text{or} \quad \frac{^{\circ}\text{F} - 32}{180} = \frac{-20}{100}$$

$$^{\circ}\text{F} - 32 = \frac{(-20)(180)}{100} = -36$$

$$^{\circ}\text{F} = -4$$

(2) To find the Reaumur temperature corresponding to  $20^{\circ}\text{F}$ :

$$\frac{^{\circ}\text{F} - 32}{180} = \frac{^{\circ}\text{Ré}}{80} = \frac{20 - 32}{180} = \frac{^{\circ}\text{Ré}}{80}$$

$$\text{i.e.,} \quad 20^{\circ}\text{F} = -5.33^{\circ}\text{Ré}$$

(3) To find the correct temperature on a thermometer reading  $80^{\circ}\text{C}$  and that shows a reading of  $-0.30^{\circ}\text{C}$  in a melting ice/water mixture and  $99.0^{\circ}\text{C}$  in steam at 760 mm pressure of mercury:

$$\frac{^{\circ}\text{C}}{100} = \frac{\text{Z} - (\text{fp})\text{“Z”}}{(\text{bp})\text{“Z”} - (\text{fp})\text{“Z”}} = \frac{80 - (-0.30)}{99.0 - (-0.30)}$$

$$\text{i.e.,} \quad ^{\circ}\text{C} = 80.87 \quad (\text{corrected})$$

### 2.1.2 Density and Specific Gravity

**2.1.2.1 Hydrometers.** Various hydrometers and the relation between the various scales.

*Alcoholometer.* This hydrometer is used in determining the density of aqueous ethyl alcohol solutions; the reading in degrees is numerically the same as the percentage of alcohol by volume. The scale known as Tralle gives the percentage by volume. Wine and Must hydrometer relations are given below.

*Ammoniameter.* This hydrometer, employed in finding the density of aqueous ammonia solutions, has a scale graduated in equal divisions from  $0^{\circ}$  to  $40^{\circ}$ . To convert the reading to specific gravity multiply by 3 and subtract the resulting number from 1000.

*Balling Hydrometer.* See under Saccharometers.

*Barkometer or Barktrometer.* This hydrometer, which is used in determining the density of tanning liquors, has a scale from  $0^{\circ}$  to  $80^{\circ}\text{Bk}$ ; the number to the right of the decimal point of a specific gravity reading is the corresponding Bk degree; thus, a specific gravity of 1.015 is  $15^{\circ}\text{Bk}$ .

**Baumé Hydrometers.** For liquids heavier than water: This hydrometer was originally based on the density of a 10% sodium chloride solution, which was given the value of 10°, and the density of pure water, which was given the value of 0°; the interval between these two values was divided into 10 equal parts. Other reference points have been taken with the result that so much confusion exists that there are about 36 different scales in use, many of which are incorrect. In general a Baumé hydrometer should have inscribed on it the temperature at which it was calibrated and also the temperature of the water used in relating the density to a specific gravity. The following expression gives the relation between the specific gravity and several of the Baumé scales:

$$\text{Specific gravity} = \frac{m}{m - \text{Baumé}}$$

$$\begin{aligned} m &= 145 \text{ at } 60^{\circ}/60^{\circ}\text{F (15.56}^{\circ}\text{C)} && \text{for the American Scale} \\ &= 144 && \text{for the old scale used in Holland} \\ &= 146.3 \text{ at } 15^{\circ}\text{C} && \text{for the Gerlach Scale} \\ &= 144.3 \text{ at } 15^{\circ}\text{C} && \text{for the Rational Scale generally used in Germany} \end{aligned}$$

For liquids lighter than water: Originally the density of a solution of 1 gram of sodium chloride in 9 grams of water at 12.5°C was given a value of 10°Bé. The scale between these points was divided into ten equal parts and these divisions were repeated throughout the scale giving a relation which could be expressed by the formula: Specific gravity = 145.88/(135.88 + Bé), which is approximately equal to 146/(136 + Bé). Other scales have since come into more general use such as that of the Bureau of Standards in which the specific gravity at 60°/60°F = 140/(130 + Bé) and that of the American Petroleum Institute (A.P.I. Scale) in which the specific gravity at 60°/60°F = 141.5/(131.5 + API°).

See also special table for conversion to density and Twaddell scale.

**Beck's Hydrometer.** This hydrometer is graduated to show a reading of 0° in pure water and a reading of 30° in a solution with a specific gravity of 0.850, with equal scale divisions above and below these two points.

**Brix Hydrometer.** See under Saccharometers.

**Cartier's Hydrometer.** This hydrometer shows a reading of 22° when immersed in a solution having a density of 22° Baumé but the scale divisions are smaller than on the Baumé hydrometer in the ratio of 16 Cartier to 15 Baumé.

**Fatty Oil Hydrometer.** The graduations on this hydrometer are in specific gravity within the range 0.908 to 0.938. The letters on the scale correspond to the specific gravity of the various common oils as follows: *R*, rape; *O*, olive; *A*, almond; *S*, sesame; *HL*, hoof oil; *HP*, hemp; *C*, cotton seed; *L*, linseed. See also Oleometer below.

**Lactometers.** These hydrometers are used in determining the density of milk. The various scales in common use are the following:

*New York Board of Health* has a scale graduated into 120 equal parts, 0° being equal to the specific gravity of water and 100° being equal to a specific gravity of 1.029.

*Quevenne* lactometer is graduated from 15° to 40° corresponding to specific gravities from 1.015 to 1.040.

*Soxhlet* lactometer has a scale from 25° to 35° corresponding to specific gravities from 1.025 to 1.035 respectively.

*Oleometer.* A hydrometer for determining the density of vegetable and sperm oils with a scale from 50° to 0° corresponding to specific gravities from 0.870 to 0.970. See also Fatty Oil Hydrometer above.

*Saccharometers.* These hydrometers are used in determining the density of sugar solutions. Solutions of the same concentration but of different carbohydrates have very nearly the same specific gravity and in general a concentration of 10 grams of carbohydrate per 100 mL of solution shows a specific gravity of 1.0386. Thus, the wt. of sugar in 1000 mL soln. is (a) for conc. < 12g/100 mL: (wt. of 1000 mL soln. - 1000) ÷ 0.386; (b) for conc. > 12g/100 mL: (wt of 1000 mL soln. - 1000) ÷ 0.385.

*Brix* hydrometer is graduated so that the number of degrees is identical with the percentage by weight of cane sugar and is used at the temperature indicated on the hydrometer.

*Balling's* saccharometer is used in Europe and is practically identical with the Brix hydrometer.

*Bates* brewers' saccharometer which is used in determining the density of malt worts is graduated so that the divisions express pounds per barrel (32 gallons). The relation between degrees Bates (=b) and degrees Balling (=B) is shown by the following formula:  $B = 260b/(360 + b)$ .

See also below under Wine and Must Hydrometer.

*Salinometer.* This hydrometer, which is used in the pickling and meat packing plants, is graduated to show percentage of saturation of a sodium chloride solution. An aqueous solution is completely saturated when it contains 26.4% pure sodium chloride. The range from 0% to 26.4% is divided into 100 parts, each division therefore representing 1% of saturation. In another type of salinometer, the degrees correspond to percentages of sodium chloride expressed in grams of sodium chloride per 100 mL of water.

*Sprayometer (Parrot and Stewart).* This hydrometer which is used in determining the density of lime sulfur solutions has two scales; one scale is graduated from 0° to 38° Baumé and the other scale is from 1.000 to 1.350 specific gravity.

*Tralle Hydrometer.* See Alcoholometer above.

*Twaddell Hydrometer.* This hydrometer, which is used only for liquids heavier than water, has a scale such that when the reading is multiplied by 5 and added to 1000 the resulting number is the specific gravity with reference to water as 1000. To convert specific gravity at 60°/60°F to Twaddell degrees, take the decimal portion of the specific gravity value and multiply it by 200; thus a specific gravity of 1.032 =  $0.032 \times 200 = 6.4^\circ$  Tw. See also special table for conversion to density and Baumé scale.

*Wine and Must Hydrometer.* This instrument has three scales. One scale shows readings of 0° to 15° Brix for sugar (see Brix Hydrometer above); another scale from 0° to 15° Tralle is used for sweet wines to indicate the percentage of alcohol by volume; and a third scale from 0° to 20° Tralle is used for tart wines to indicate the percentage of alcohol by volume.

**2.1.2.2 Conversion of Specific Gravity at 25°/25°C to Density at any Temperature from 0° to 40°C.\*** Liquids change volume with change in temperature, but the amount of this change,  $\beta$  (coefficient of cubical expansion), varies widely with different liquids, and to some extent for the same liquid at different temperatures.

The table below, which is calculated from the relationship:

$$F_{\beta_t} = \frac{\text{density of water at } 25^\circ\text{C} (=0.99705)}{1 - \beta(25 - t)} \quad (2.1)$$

\* Cf. Dreisbach, *Ind. Eng. Chem., Anal. Ed.* 12:160 (1940).

may be used to find  $d^t$ , the density (weight of 1 mL) of a liquid at any temperature ( $t$ ) between  $0^\circ$  and  $40^\circ\text{C}$  if the specific gravity at  $25^\circ/25^\circ\text{C}$  ( $S$ ) and the coefficient of cubical expansion ( $\beta$ ) are known. Substitutions are made in the equations:

$$d^t = SF_{\beta_t} \tag{2.2}$$

$$S = \frac{d^t}{F_{\beta_t}} \tag{2.3}$$

Factors ( $F_{\beta_t}$ )

$Density\ t^\circ\text{C} = sp.\ gr.\ 25^\circ/25^\circ \times F_{\beta_t}$

\*  $\beta$  = coefficient of cubical expansion.

*Examples.* All examples are based upon an assumed coefficient of cubical expansion,  $\beta$ , of  $1.3 \times 10^{-3}$ .

*Example 1.* To find the density of a liquid at  $20^\circ\text{C}$ ,  $d^{20}$ , which has a specific gravity ( $S$ ) of  $1.2500^{25}_{25}$ :

From the table above  $F_{\beta_t}$  at  $20^\circ\text{C} = 1.0036$ .

$$d^{20} = d^t = SF_{\beta_t} = 1.2500 \times 1.0036 = 1.2545$$

*Example 2.* To find the density at  $20^\circ\text{C}$  ( $d^{20}$ ) of a liquid which has a specific gravity of  $1.2500^{17}_{4}$ :

Since the density of water at  $4^\circ\text{C}$  is equal to 1, specific gravity at  $17^\circ/4^\circ = d^{17} = 1.2500$ .  
Substitution in Equation 3 with  $F_{\beta_t}$  at  $17^\circ\text{C}$ , by interpolation from the table, equal to 1.00756, gives

$$Sp.\ gr.\ 25^\circ/25^\circ = S = 1.2500 \div 1.00756$$

Substitution of this value for  $S$  in Equation 2 with  $F_{\beta_t}$  at  $20^\circ\text{C}$ , from the table, equal to 1.0036, gives

$$d^{20} = d^t = (1.2500 \div 1.00756) \times 1.0036 = 1.2451$$

*Example 3.* To find the specific gravity at  $20^{\circ}/4^{\circ}\text{C}$  of a liquid which has a specific gravity of  $1.2500_{\frac{25}{4}}$ :

Since the density of water at  $4^{\circ}\text{C}$ , is equal to 1, specific gravity  $25^{\circ}/4^{\circ} = d^{25} = 1.2500$ ; and, specific gravity  $20^{\circ}/4^{\circ} = d^{20}$ .

Substitution in Equation 3, with  $d^t = 1.2500$ ; and, with  $F_{\beta_t}$  at  $25^{\circ}\text{C}$ , from the table, equal to 0.99705, gives

$$\text{Sp. gr. } 25^{\circ}/25^{\circ} = S = 1.2500 \div 0.99705$$

Substitution of this value for  $S$  in Equation 2, with  $F_{\beta_t}$  at  $20^{\circ}\text{C}$ , from the table, equal to 1.0036, gives

$$\text{Sp. gr. } 20^{\circ}/4^{\circ} = d^{20} = (1.2500 \div 0.99705) \times 1.0036 = 1.2582$$

*Example 4.* To find the density at  $25^{\circ}\text{C}$  of a liquid which has a specific gravity of  $1.2500_{\frac{15}{15}}$ :

Since the density of water at  $15^{\circ}\text{C} = 0.99910$ ,

$$d^{15} = \text{sp. gr. } 15^{\circ}/15^{\circ} \times 0.99910 = 1.2500 \times 0.99910$$

Substitution in Equation 3, with  $F_{\beta_t}$  at  $15^{\circ}\text{C}$ , from the table, equal to 1.0102, gives

$$\text{Sp. gr. } 25^{\circ}/25^{\circ} = S = (1.2500 \times 0.99910) \div 1.0102$$

Substitution of this value for  $S$  in Equation 2, with  $F_{\beta_t}$  at  $25^{\circ}$ , from the table, equal to 0.99705, gives

$$d^{26} = d^t = (1.2500 \times 0.99910 \div 1.0102) \times 0.99705 = 1.2326$$

### 2.1.3 Barometry and Barometric Corrections

In principle, the mercurial barometer balances a column of pure mercury against the weight of the atmosphere. The height of the column above the level of the mercury in the reservoir can be measured and serves as a direct index of atmospheric pressure. The space above the mercury in a barometer tube should be a Torricellian vacuum, perfect except for the practically negligible vapor pressure of mercury. The perfection of the vacuum is indicated by the sharpness of the click noted when the barometer tube is inclined. A barometer should be in a vertical position, suspended rather than fastened to a wall, and in a good light but not exposed to direct sunlight or too near a source of heat. The standard conditions for barometric measurements are  $0^{\circ}\text{C}$  and gravity as at  $45^{\circ}$  latitude and sea level. There are numerous sources of error, but corrections for most of these are readily applied. Some of the corrections are very small, and their application may be questionable in view of the probably larger errors. The degree of consistency to be expected in careful measurements is about 0.13 mm with a 6.4-mm tube, increasing to 0.04 mm with a tube 12.7 mm in diameter.

In reading a barometer of the Fortin type (the usual laboratory instrument for precision measurements), the procedure should be as follows: (1) Observe and record the temperature as indicated by the thermometer attached to the barometer. The temperature correction is very important and may be affected by heat from the observer's body. (2) Set the mercury in the reservoir at zero level, so that the point of the pin above the mercury just touches the surface, making a barely noticeable dimple therein. Tap the tube at the top and verify the zero setting. (3) Bring the vernier down until the view at the light background is cut off at the highest point of the meniscus. Record the reading.

The corrections to be made on the reading are as follows: (1) Temperature, to correct for the difference in thermal expansion of the mercury and the brass (or glass) to which the scale is attached.

This correction converts the reading into the value of 0°C. The brass scale table is applicable to the Fortin barometer. See Tables 2.10 latitude-gravity correction, and 2.11 altitude-gravity correction, to compensate for differences in gravity, which would affect the height of the mercury column by variation in mass. If local gravity is unknown, an approximate correction may be made from the tables. Local values of gravity are often subject to irregularities which lead to errors even when the corrections here provided are made. It is, therefore, advisable to determine the local value of gravity, from which the correction can be effected in the following manner:

$$Bt = Br + \left( \frac{g_1 - g_0}{g_0} \right) \times Br$$

in which  $Bt$  and  $Br$  are the true and the observed heights of the barometer, respectively.  $g_0$  is standard gravity ( $980\,665\text{ cm} \cdot \text{s}^{-2}$ ), and  $g_1$  is the local gravity. It may be noted that for most localities,  $g_1$  is smaller than  $g_0$ , which makes the correction negative. These corrections compensate the reading to gravity at 45° latitude and sea level. (3) Correction for capillary depression of the level of the meniscus. This varies with the tube diameter and actual height of the meniscus in a particular case. Some barometers are calibrated to allow for an average value of the latter and approximating the correction. See table. (4) Correction for vapor pressure of mercury. This correction is usually negligible, being only 0.001 mm at 20°C and 0.006 mm at 40°C. This correction is added. See table of vapor pressure of mercury.

The corrections above do not apply to aneroid barometers. These instruments should be calibrated at regular intervals by checking them against a corrected mercurial barometer.

For records on weather maps, meteorologists customarily correct barometer readings to sea level, and some barometers may be calibrated accordingly. Such instruments are not suitable for laboratory use where true pressure under standard conditions is required. Scale corrections should be specified in the maker's instructions with the instrument, and are also indicated by the lack of correspondence between a gauge mark usually placed exactly 76.2 cm from the zero point and the 76.2-cm scale graduation.

**TABLE 2.9** Barometer Temperature Correction—Metric Units

The values in the table below are to be subtracted from the observed readings to correct for the difference in the expansion of the mercury and the glass scale at different temperatures.

| A. Glass scale |                                          |      |      |      |      |      |      |
|----------------|------------------------------------------|------|------|------|------|------|------|
| Temp.<br>°C.   | Observed barometer height in millimeters |      |      |      |      |      |      |
|                | 700                                      | 730  | 740  | 750  | 760  | 770  | 800  |
|                | mm.                                      | mm.  | mm.  | mm.  | mm.  | mm.  | mm.  |
| 0              | 0.00                                     | 0.00 | 0.00 | 0.00 | 0.00 | 0.00 | 0.00 |
| 1              | 0.12                                     | 0.13 | 0.13 | 0.13 | 0.13 | 0.13 | 0.14 |
| 2              | 0.24                                     | 0.25 | 0.26 | 0.26 | 0.26 | 0.27 | 0.27 |
| 3              | 0.36                                     | 0.38 | 0.38 | 0.39 | 0.40 | 0.40 | 0.42 |
| 4              | 0.49                                     | 0.51 | 0.51 | 0.52 | 0.53 | 0.53 | 0.55 |
| 5              | 0.61                                     | 0.63 | 0.64 | 0.65 | 0.66 | 0.67 | 0.69 |
| 6              | 0.73                                     | 0.76 | 0.77 | 0.78 | 0.79 | 0.80 | 0.83 |
| 7              | 0.85                                     | 0.89 | 0.90 | 0.91 | 0.92 | 0.93 | 0.97 |
| 8              | 0.97                                     | 1.01 | 1.03 | 1.04 | 1.05 | 1.07 | 1.11 |

**TABLE 2.11** Barometric Correction for Gravity—Metric Units

The values in the table below are to be subtracted from the readings taken on a mercurial barometer to correct for the decrease in gravity with increase in altitude.

[illegible]

**TABLE 2.12** Reduction of the Barometer to Sea Level—Metric Units

A barometer located at an elevation above sea level will show a reading lower than a barometer at sea level by an amount approximately 2.5 mm (0.1 in) for each 30.5 m (100 ft) of elevation. A closer approximation can be made by reference to the following tables, which take into account (1) the effect of altitude of the station at which the barometer is read, (2) the mean temperature of the air column extending from the station down to sea level, (3) the latitude of the station at which the barometer is read, and (4) the reading of the barometer corrected for its temperature, a correction which is applied only to mercurial barometers since the aneroid barometers are compensated for temperature effects.

*Example.* A barometer which has been corrected for its temperature reads 650 mm at a station whose altitude is 1350 m above sea level and at a latitude of 30°. The mean temperature (outdoor temperature) at the station is 20°C.

Table A (metric units) gives for these conditions a temperature-altitude factor of ..... 135.2  
The Latitude Factor Table gives for 135.2 at 30° lat. a correction of ..... +0.17  
Therefore, the corrected value of the temperature-altitude factor is ..... 135.37

Entering Table B (metric units), with a temperature-altitude factor of 135.37 and a barometric reading of 650 mm (corrected for temperature), the correction is found to be ..... 109.6  
Accordingly the barometric reading reduced to sea level is 650 + 109.6 = 759.6 mm.

**Latitude Factor—English or Metric Units.** For latitudes 0°–45° add the latitude factor, for 45°–90° subtract the latitude factor, from the values obtained in Table A.

| Temp.—Alt.<br>Factor<br>From Table A | Latitude |     |     |     |     |
|--------------------------------------|----------|-----|-----|-----|-----|
|                                      | 0°       | 10° | 20° | 30° | 45° |

**TABLE 2.13** Viscosity Conversion Table  
*Centistokes to Saybolt, Redwood, and Engler units.*

Poise = cgs unit of absolute viscosity      Centipoise = 0.01 poise

Stoke = cgs unit of kinematic viscosity      Centistoke = 0.01 stoke

Centipoises = centistokes × density (at temperature under consideration)

Reyn (1 lb · s per sq in) = 69 × 10<sup>5</sup> centipoises

| 50.0        | 232.1                          | 232.5  | 233.8  | 203.3              | 204.7  | 208.3  | 6.63                               |
| 60.0        | 278.3                          | 278.8  | 280.2  | 243.5              | 245.3  | 250.0  | 7.90                               |
| 70.0        | 324.4                          | 325.0  | 326.7  | 283.9              | 286.0  | 291.7  | 9.21                               |
| 80.0        | 370.8                          | 371.5  | 373.4  | 323.9              | 326.6  | 333.4  | 10.53                              |
| 90.0        | 417.1                          | 417.9  | 420.0  | 364.4              | 367.4  | 375.0  | 11.84                              |
| 100.0*      | 463.5                          | 464.4  | 466.7  | 404.9              | 408.2  | 416.7  | 13.16                              |

\* At higher values use the same ratio as above for 100 centistokes; **e.g.**, 102 centistokes = 102 × 4.635 Saybolt seconds at 100°F.  
To obtain the Saybolt Universal viscosity equivalent to a kinematic viscosity determined at *t*°F., multiply the equivalent Saybolt Universal viscosity at 100°F. by 1 + (t – 100) 0.000064; **e.g.**, 10 centistokes at 210°F are equivalent to 58.91 × 1.0070, or 59.32 Saybolt Universal Viscosity at 210°F.

**TABLE 2.14** Conversion of Weighings in Air to Weighings in Vacuo

If the mass of a substance in air is  $m_f$ , its density  $\rho_m$ , the density of weights used in making the weighing  $\rho_w$ , and the density\* of air  $\rho_a$ , the true mass of the substance in vacuo,  $m_{vac}$ , is

$$m_{vac} = m_f + \rho_a m_f \left( \frac{1}{\rho_m} - \frac{1}{\rho_w} \right)$$

For most purposes it is sufficient to assume a density of 8.4 for brass weights, and a density of 0.0012 for air under ordinary conditions. The equation then becomes

$$m_{vac} = m_f + 0.0012 m_f \left( \frac{1}{\rho_m} - \frac{1}{8.4} \right)$$

The table which follows gives the values of  $k$  (buoyancy reduction factor), which is the correction necessary because of the buoyant effect of the air upon the object weighed; the table is computed for air with the density of 0.0012;  $m$  is the weight in grams of the object when weighed in air; weight of object reduced to “in vacuo” =  $m + km/1000$ .

| Density of<br>object weighed | Buoyancy reduction factor, $k$  |                                        |                                        |                               |
|------------------------------|---------------------------------|----------------------------------------|----------------------------------------|-------------------------------|

TABLE 2.15 Hydrometer Conversion Table

This table gives the relation between density (c.g.s.) and degrees on the Baumé and Twaddell scales. The Twaddell scale is never used for densities less than unity. See also Sec. 2.1.2.1, Hydrometers.

| Density | Degrees Baumé<br>(NIST* scale) | Degrees Baumé<br>(A.P.I.† scale) | Density                      | Degrees Baumé<br>(NIST* scale) | Degrees Baumé<br>(A.P.I.† scale) |
|---------|--------------------------------|----------------------------------|------------------------------|--------------------------------|----------------------------------|

TABLE 2.18 Molar Equivalent of One Liter of Gas at Various Temperatures and Pressures

The values in this table, which give the number of moles in 1 liter of gas, are based on the properties of an “ideal” gas and were calculated by use of the formula:

Moles/liter =  $\frac{P}{760} \times \frac{273}{T} \times \frac{1}{22.40}$

where *P* is the pressure in millimeters of mercury and *T* is the temperature in kelvins (= *t*°C + 273).  
To convert to moles per cubic foot multiply the values in the table by 28.316.

| Pressure<br>mm of<br>mercury | Temperature °C |         |         |         |         |         |

**TABLE 2.19** Factors for Reducing Gas Volumes to Normal (Standard) Temperature and Pressure (760 mmHg)

*Examples:* (a) 20 mL of dry gas at 22°C and 730 mm =  $20 \times 0.8888 = 17.78$  mL at 0°C and 760 mm. (b) 20 mL of a gas over water at 22° and 730 mm =  $20 \times$  (factor corrected for aqueous tension; i.e., 730 – 19.8 or 710.2 mm) = 20 mL of dry gas at 22° and 710.2 mm =  $20 \times 0.86475 = 17.30$  mL at 0°C and 760 mm. Mass in milligrams of 1 mL of gas at S.T.P.: acetylene, 1.173; carbon dioxide, 1.9769; hydrogen, 0.0899; nitric oxide (NO), 1.3402; nitrogen, 1.25057; oxygen, 1.42904.

| Pressure<br>mm of<br>mercury | Temperature °C |        |        |        |        |        |        |        |

**TABLE 2.20** Values of Absorbance for Percent Absorption

To convert percent absorption (% A) to absorbance, find the present absorption to the nearest whole digit in the left-hand column; read across to the column located under the tenth of a percent desired, and read the value of absorbance. The value of absorbance corresponding to 26.8% absorption is thus 0.1355.

| % A  | .0    | .1    | .2    | .3    | .4    | .5    | .6    | .7    | .8    | .9    |

**TABLE 2.21** Transmittance-Absorbance Conversion Table

*From Meites, Handbook of Analytical Chemistry, 1963, McGraw-Hill Book Company; by permission.*

This table gives absorbance values to four significant figures corresponding to % transmittance values which are given to three significant figures. The values of % transmittance are given in the left-hand column and in the top row. For example, 8.4% transmittance corresponds to an absorbance of 1.076.

Interpolation is facilitated and accuracy is maximized if the % transmittance is between 1 and 10, by multiplying its value by 10, finding the absorbance corresponding to the result, and adding 1. For example, to find the absorbance corresponding to 8.45% transmittance, note that 84.5% transmittance corresponds to an absorbance of 0.0731, so that 8.45% transmittance corresponds to an absorbance of 1.0731. For % transmittance values between 0.1 and 1, multiply by 100, find the absorbance corresponding to the result, and add 2.

Conversely, to find the % transmittance corresponding to an absorbance between 1 and 2, subtract 1 from the absorbance, find the % transmittance corresponding to the result, and divide by 10. For example, an absorbance of 1.219 can best be converted to % transmittance by noting that an absorbance of 0.219 would correspond to 60.4% transmittance; dividing this by 10 gives the desired value, 6.04% transmittance. For absorbance values between 2 and 3, subtract 2 from the absorbance, find the % transmittance corresponding to the result, and divide by 100.

| % Transmittance | 0.0    | 0.1    | 0.2    | 0.3    | 0.4    | 0.5    | 0.6    | 0.7    | 0.8    | 0.9    |

## 2.2 MATHEMATICAL TABLES

---

### 2.2.1 Logarithms

#### 2.2.1.1 Properties and Uses

*Definition of Logarithm.* The *logarithm*  $x$  of the number  $N$  to the base  $b$  is the exponent of the power to which  $b$  must be raised to give  $N$ . That is,

$$\log_b N = x \quad \text{or} \quad b^x = N$$

The number  $N$  is positive and  $b$  may be any positive number except 1.

*Properties of Logarithms*

1. The logarithm of a product is equal to the sum of the logarithms of the factors; thus,

$$\log_b M \cdot N = \log_b M + \log_b N$$

2. The logarithm of a quotient is equal to the logarithm of the numerator minus the logarithm of the denominator; thus,

$$\log_b \frac{M}{N} = \log_b M - \log_b N$$

3. The logarithm of a power of a number is equal to the logarithm of the base multiplied by the exponent of the power; thus,

$$\log_b M^p = p \cdot \log_b M$$

4. The logarithm of a root of a number is equal to the logarithm of the number divided by the index of the root; thus

$$\log_b \sqrt[q]{M} = \frac{1}{q} \log_b M$$

Other properties of logarithms:

$$\log_b b = 1 \quad \log_b \sqrt[q]{M^p} = \frac{p}{q} \log_b M$$

$$\log_b 1 = 0 \quad \log_b N = \log_a N \cdot \log_b a = \frac{\log_a N}{\log_a b}$$

$$\log_b (b^N) = N \quad b^{\log_b N} = N$$

*Systems of Logarithms.* There are two common systems of logarithms in use: (1) the *natural* (Napierian or hyperbolic) system which uses the base  $e = 2.71828 \dots$ ; (2) the *common* (Briggsian) system which uses the base 10.

We shall use the abbreviation  $\log N \equiv \log_{10} N$  in this section.

Unless otherwise stated, tables of logarithms are always tables of common logarithms.

*Characteristic of a Common Logarithm of a Number.* Every real positive number has a real common logarithm such that if  $a < b$ ,  $\log a < \log b$ . Neither zero nor any negative number has a real logarithm.

A common logarithm, in general, consists of an integer, which is called the *characteristic*, and a decimal (usually endless), which is called the *mantissa*. The characteristic of any number may be determined from the following rules:

*Rule I.* The characteristic of any number greater than 1 is one less than the number of digits before the decimal point.

*Rule II.\** The characteristic of a number less than 1 is found by subtracting from 9 the number of ciphers between the decimal point and the first significant digit, and writing  $-10$  after the result.

Thus the characteristic of  $\log 936$  is 2; the characteristic of  $\log 9.36$  is 0; of  $\log 0.936$  is  $9 - 10$ ; of  $\log 0.00936$  is  $7 - 10$ .

*Mantissa of a Common Logarithm of a Number.* An important consequence of the use of base 10 is that the mantissa of a number is independent of the position of the decimal point. Thus 93 600, 93.600, 0.000 936, all have the same mantissa. Hence in Tables of Common Logarithms only mantissas are given. A five-place table gives the values of the mantissa correct to five places of decimals.

Since it is possible to obtain logarithms by using hand calculators, this Handbook contains no logarithm tables.

#### *Helpful Hints*

1. When connecting numbers to logarithms, use as many decimal places in the mantissa as there are significant digits in the number.
2. When finding the antilogarithm, keep as many significant digits as there are decimal places in the mantissa.

*Examples:*  $\log 10.35 = 1.0149$ ;  $\text{antilog } 0.065 = 1.16$ .

---

\* Some writers use a dash over the characteristic to indicate a negative value; for example,

$$\log 0.004657 = 7.6681 - 10 = \bar{3}.6681$$

**TABLE 2.23** Derivatives and Differentiation*Rules for differentiation.*

From Baumeister and Marks, *Standard Handbook for Mechanical Engineers*, 7th ed., McGraw-Hill Book Company, New York (1967); by permission.

To find the derivative of a given function at a given point: (1) If the function is given only by a curve, measure graphically the slope of the tangent at the point in question; (2) if the function is given by a mathematical expression, use the following rules for differentiation. These rules give, directly, the differential,  $dy$ , in terms of  $dx$ ; to find the derivative,  $dy/dx$ , divide through by  $dx$ .

Here  $u, v, w, \dots$  represents any functions of a variable  $x$ , or may themselves be independent variables.  $a$  is a constant which does not change in values in the same discussion;  $e = 2.71828$ .

1.  $d(a + u) = du$

2.  $d(au) = a du$

3.  $d(u + v + w + \dots) = du + dv + dw + \dots$

4.  $d(uv) = u dv + v du$

5.  $d(uvw \dots) = (uvw \dots) \left( \frac{du}{u} + \frac{dv}{v} + \frac{dw}{w} + \dots \right)$

6.  $\frac{d}{dv} \frac{u}{v} = \frac{v du - u dv}{v^2}$

7.  $d(u^m) = mu^{m-1} du$

Thus,  $d(u^2) = 2u du$ ;  $d(u^3) = 3u^2 du$ ; etc.

8.  $d\sqrt{u} = \frac{du}{2\sqrt{u}}$

9.  $d\left(\frac{1}{u}\right) = -\frac{du}{u^2}$

10.  $d(e^u) = e^u du$

11.  $d(a^u) = (\ln a)a^u du$

12.  $d \ln u = \frac{du}{u}$

13.  $d \log_{10} u = (\log_{10} e) \frac{du}{u} = (0.4343 \dots) \frac{du}{u}$

14.  $d \sin u = \cos u du$

15.  $d \csc u = -\cot u \csc u du$

16.  $d \cos u = -\sin u du$

17.  $d \sec u = \tan u \sec u du$

18.  $d \tan u = \sec^2 u du$

19.  $d \cot u = -\csc^2 u du$

20.  $d \sin^{-1} u = \frac{du}{\sqrt{1-u^2}}$

21.  $d \csc^{-1} u = -\frac{du}{u\sqrt{u^2-1}}$

22.  $d \cos^{-1} u = -\frac{du}{\sqrt{1-u^2}}$

23.  $d \sec^{-1} u = \frac{du}{u\sqrt{u^2-1}}$

24.  $d \tan^{-1} u = \frac{du}{1+u^2}$

25.  $d \cot^{-1} u = -\frac{du}{1+u^2}$

26.  $d \ln \sin u = \cot u du$

27.  $d \ln \tan u = \frac{2 du}{\sin 2u}$

28.  $d \ln \cos u = -\tan u du$

29.  $d \ln \cot u = -\frac{2 du}{\sin 2u}$

30.  $d \sinh u = \cosh u du$

31.  $d \operatorname{csch} u = -\operatorname{csch} u \coth u du$

32.  $d \cosh u = \sinh u du$

33.  $d \operatorname{sech} u = -\operatorname{sech} u \tanh u du$

34.  $d \tanh u = \operatorname{sech}^2 u du$

35.  $d \coth u = -\operatorname{csch}^2 u du$

36.  $d \sinh^{-1} u = \frac{du}{\sqrt{u^2+1}}$

37.  $d \operatorname{csch}^{-1} u = -\frac{du}{u\sqrt{u^2+1}}$

38.  $d \cosh^{-1} u = \frac{du}{\sqrt{u^2-1}}$

39.  $d \operatorname{sech}^{-1} u = -\frac{du}{u\sqrt{1-u^2}}$

40.  $d \tanh^{-1} u = \frac{du}{1-u^2}$

41.  $d \coth^{-1} u = \frac{du}{1-u^2}$

42.  $d(u^v) = (u^{v-1})(u \ln u dv + v du)$

**TABLE 2.24** Integrals

From *Baumeister and Marks, Standard Handbook for Mechanical Engineers, 7th ed., McGraw-Hill Book Company, New York (1967); by permission.*

An integral of  $f(x) dx$  is any function whose differential is  $f(x) dx$ , and is denoted by  $\int f(x) dx$ . All the integrals of  $f(x) dx$  are included in the expression  $\int f(x) dx + C$ , where  $\int f(x) dx$  is any particular integral, and  $C$  is an arbitrary constant. The process of finding (when possible) an integral of a given function consists in recognizing by inspection a function which, when differentiated, will produce the given function; or in transforming the given function into a form in which such recognition is easy. The most common integrable forms are collected in the following brief table; for a more extended list, see Peirce, *Table of Integrals*, Ginn, or Dwight, *Table of Integrals and other Mathematical Data*, Macmillan.

## General formulas

1.  $\int a du = a \int du = au + C$
2.  $\int (u + v) dx = \int u dx + \int v dx$
3.  $\int u dv = uv - \int v du$
4.  $\int f(x) dx = \int f[F(y)]F'(y) dy, x = F(y)$
5.  $\int dy \int f(x, y) dx = \int dx \int f(x, y) dy$

## Fundamental integrals

6.  $\int x^n dx = \frac{x^{n+1}}{n+1} + C$ , when  $n \neq -1$
7.  $\int \frac{dx}{x} = \ln x + C = \ln cx$
8.  $\int e^x dx = e^x + C$
9.  $\int \sin x dx = -\cos x + C$
10.  $\int \cos x dx = \sin x + C$
11.  $\int \frac{dx}{\sin^2 x} = -\cot x + C$
12.  $\int \frac{dx}{\cos^2 x} = \tan x + C$
13.  $\int \frac{dx}{\sqrt{1-x^2}} = \sin^{-1} x + C = -\cos^{-1} x + C$
14.  $\int \frac{dx}{1+x^2} = \tan^{-1} x + C = -\cot^{-1} x + C$

## Rational functions

15.  $\int (a + bx)^n dx = \frac{(a + bx)^{n+1}}{(n+1)b} + C$
  16.  $\int \frac{dx}{a + bx} = \frac{1}{b} \ln(a + bx) + C = \frac{1}{b} \ln c(a + bx)$
  17.  $\int \frac{1}{x^2} dx = -\frac{1}{x} + C$
  18.  $\int \frac{dx}{(a + bx)^2} = -\frac{1}{b(a + bx)} + C$
  19.  $\int \frac{dx}{1-x^2} = \frac{1}{2} \ln \frac{1+x}{1-x} + C = \tanh^{-1} x + C$ , when  $x < 1$
  20.  $\int \frac{dx}{x^2 - 1} = \frac{1}{2} \ln \frac{x-1}{x+1} + C = -\coth^{-1} x + C$ , when  $x > 1$
  21.  $\int \frac{dx}{a + bx^2} = \frac{1}{\sqrt{ab}} \tan^{-1} \left( \sqrt{\frac{b}{a}} x \right) + C$
  22.  $\int \frac{dx}{a - bx^2} = \frac{1}{2\sqrt{ab}} \ln \frac{\sqrt{ab} + bx}{\sqrt{ab} - bx} + C$
- $\left. \begin{aligned} &= \frac{1}{\sqrt{ab}} \tanh^{-1} \left( \sqrt{\frac{b}{a}} x \right) + C \end{aligned} \right\} [a > 0, b > 0]$

**TABLE 2.24** Integrals (Continued)Rational functions (*continued*)

23. 
$$\int \frac{dx}{a + 2bx + cx^2} = \frac{1}{\sqrt{ac - b^2}} \tan^{-1} \frac{b + cx}{\sqrt{ac - b^2}} + C \left\{ [ac - b^2 > 0] \right.$$
- $$= \frac{1}{2\sqrt{b^2 - ac}} \ln \frac{\sqrt{b^2 - ac} - b - cx}{\sqrt{b^2 - ac} + b + cx} + C$$
- $$= -\frac{1}{\sqrt{b^2 - ac}} \tanh^{-1} \frac{b + cx}{\sqrt{b^2 - ac}} + C \left. \right\} [b^2 - ac > 0]$$
24. 
$$\int \frac{dx}{a + 2bx + cx^2} = -\frac{1}{b + cx} + C, \text{ when } b^2 = ac$$
25. 
$$\int \frac{(m + nx) dx}{a + 2bx + cx^2} = \frac{n}{2c} \ln(a + 2bx + cx^2) + \frac{mc - nb}{c} \int \frac{dx}{a + 2bx + cx^2}$$
26. In  $\int \frac{f(x) dx}{a + 2bx + cx^2}$ , if  $f(x)$  is a polynomial of higher than the first degree, divide by the denominator before integrating.
27. 
$$\int \frac{dx}{(a + 2bx + cx^2)^p} = \frac{1}{2(ac - b^2)(p - 1)} \times \frac{b + cx}{(a + 2bx + cx^2)^{p-1}}$$

$$+ \frac{(2p - 3)c}{2(ac - b^2)(p - 1)} \int \frac{dx}{(a + 2bx + cx^2)^{p-1}}$$
28. 
$$\int \frac{(m + nx) dx}{(a + 2bx + cx^2)^p} = -\frac{n}{2c(p - 1)} \times \frac{1}{(a + 2bx + cx^2)^{p-1}}$$

$$+ \frac{mc - nb}{c} \int \frac{dx}{(a + 2bx + cx^2)^p}$$
29. 
$$\int x^{m-1}(a + bx)^n dx = \frac{x^{m-1}(a + bx)^{n+1}}{(m + n)b} - \frac{(m - 1)a}{(m + n)b} \int x^{m-2}(a + bx)^n dx$$

$$= \frac{x^m(a + bx)^n}{m + n} + \frac{na}{m + n} \int x^{m-1}(a + bx)^{n-1} dx$$

## Irrational functions

30. 
$$\int \sqrt{a + bx} dx = \frac{2}{3b} \sqrt{(a + bx)^3} + C$$
31. 
$$\int \frac{dx}{\sqrt{a + bx}} = \frac{2}{b} \sqrt{a + bx} + C$$
32. 
$$\int \frac{(m + nx) dx}{\sqrt{a + bx}} = \frac{2}{3b^2} (3mb - 2an + nbx) \sqrt{a + bx} + C$$
33. 
$$\int \frac{dx}{(m + nx) \sqrt{a + bx}}$$
; substitute  $y = \sqrt{a + bx}$ , and use 21 and 22
34. 
$$\int \frac{f(x, \sqrt[n]{a + bx})}{F(x, \sqrt[n]{a + bx})} dx$$
; substitute  $\sqrt[n]{a + bx} = y$
35. 
$$\int \frac{dx}{\sqrt{a^2 - x^2}} = \sin^{-1} \frac{x}{a} + C = -\cos^{-1} \frac{x}{a} + C$$
36. 
$$\int \frac{dx}{\sqrt{a^2 + x^2}} = \ln(x + \sqrt{a^2 + x^2}) + C = \sinh^{-1} \frac{x}{a} + C$$
37. 
$$\int \frac{dx}{\sqrt{x^2 - a^2}} = \ln(x + \sqrt{x^2 - a^2}) + C = \cosh^{-1} \frac{x}{a} + C$$

**TABLE 2.24** Integrals (*Continued*)Irrational functions (*continued*)

38.  $\int \frac{dx}{\sqrt{a+2bx+cx^2}} = \frac{1}{\sqrt{c}} \ln(b+cx+\sqrt{c}\sqrt{a+2bx+cx^2}) + C$ , when  $c > 0$   
 $= \frac{1}{\sqrt{c}} \sinh^{-1} \frac{b+cx}{\sqrt{ac-b^2}} + C$ , when  $ac-b^2 > 0$   
 $= \frac{1}{\sqrt{c}} \cosh^{-1} \frac{b+cx}{\sqrt{b^2-ac}} + C$ , when  $b^2-ac > 0$   
 $= \frac{-1}{\sqrt{-c}} \sin^{-1} \frac{b+cx}{\sqrt{b^2-ac}} + C$ , when  $c < 0$
39.  $\int \frac{(m+nx) dx}{\sqrt{a+2bx+cx^2}} = \frac{n}{c} \sqrt{a+2bx+cx^2} + \frac{mc-nb}{c} \int \frac{dx}{\sqrt{a+2bx+cx^2}}$
40.  $\int \frac{x^m dx}{\sqrt{a+2bx+cx^2}} = \frac{x^{m-1} X}{mc} - \frac{(m-1)a}{mc} \int \frac{x^{m-2} dx}{X} - \frac{(2m-1)b}{mc} \int \frac{x^{m-1} dx}{X}$ ,  
 when  $X = \sqrt{a+2bx+cx^2}$
41.  $\int \sqrt{a^2+x^2} dx = \frac{x}{2} \sqrt{a^2+x^2} + \frac{a^2}{2} \ln(x+\sqrt{a^2+x^2}) + C$   
 $= \frac{x}{2} \sqrt{a^2+x^2} + \frac{a^2}{2} \sinh^{-1} \frac{x}{a} + C$
42.  $\int \sqrt{a^2-x^2} dx = \frac{x}{2} \sqrt{a^2-x^2} + \frac{a^2}{2} \sin^{-1} \frac{x}{a} + C$
43.  $\int \sqrt{x^2-a^2} dx = \frac{x}{2} \sqrt{x^2-a^2} - \frac{a^2}{2} \ln(x+\sqrt{x^2-a^2}) + C$   
 $= \frac{x}{2} \sqrt{x^2-a^2} - \frac{a^2}{2} \cosh^{-1} \frac{x}{a} + C$
44.  $\int \sqrt{a+2bx+cx^2} dx = \frac{b+cx}{2c} \sqrt{a+2bx+cx^2}$   
 $+ \frac{ac-b^2}{2c} \int \frac{dx}{\sqrt{a+2bx+cx^2}} + C$

## Transcendental functions

45.  $\int a^x dx = \frac{a^x}{\ln a} + C$
46.  $\int x^n e^{ax} dx = \frac{x^n e^{ax}}{a} \left[ 1 - \frac{n}{ax} + \frac{n(n-1)}{a^2 x^2} - \cdots \pm \frac{n!}{a^n x^n} \right] + C$
47.  $\int \ln x dx = x \ln x - x + C$
48.  $\int \frac{\ln x}{x^2} dx = -\frac{\ln x}{x} - \frac{1}{x} + C$
49.  $\int \frac{(\ln x)^n}{x} dx = \frac{1}{n+1} (\ln x)^{n+1} + C$
50.  $\int \sin^2 x dx = -\frac{1}{4} \sin 2x + \frac{1}{2} x + C = -\frac{1}{2} \sin x \cos x + \frac{1}{2} x + C$
51.  $\int \cos^2 x dx = \frac{1}{4} \sin 2x + \frac{1}{2} x + C = \frac{1}{2} \sin x \cos x + \frac{1}{2} x + C$
52.  $\int \sin mx dx = -\frac{\cos mx}{m} + C$
53.  $\int \cos mx dx = \frac{\sin mx}{m} + C$

**TABLE 2.24** Integrals (*Continued*)Transcendental functions (*continued*)

- 
54.  $\int \sin mx \cos nx \, dx = -\frac{\cos(m+n)x}{2(m+n)} - \frac{\cos(m-n)x}{2(m-n)} + C$
55.  $\int \sin mx \sin nx \, dx = \frac{\sin(m-n)x}{2(m-n)} - \frac{\sin(m+n)x}{2(m+n)} + C$
56.  $\int \cos mx \cos nx \, dx = \frac{\sin(m-n)x}{2(m-n)} + \frac{\sin(m+n)x}{2(m+n)} + C$
57.  $\int \tan x \, dx = -\ln \cos x + C$
58.  $\int \cot x \, dx = \ln \sin x + C$
59.  $\int \frac{dx}{\sin x} = \ln \tan \frac{x}{2} + C$
60.  $\int \frac{dx}{\cos x} = \ln \tan \left( \frac{\pi}{4} + \frac{x}{2} \right) + C$
61.  $\int \frac{dx}{1 + \cos x} = \tan \frac{x}{2} + C$
62.  $\int \frac{dx}{1 - \cos x} = -\cot \frac{x}{2} + C$
63.  $\int \sin x \cos x \, dx = \frac{1}{2} \sin^2 x + C$
64.  $\int \frac{dx}{\sin x \cos x} = \ln \tan x + C$
- 65.\*  $\int \sin^n x \, dx = -\frac{\cos x \sin^{n-1} x}{n} + \frac{n-1}{n} \int \sin^{n-2} x \, dx$
- 66.\*  $\int \cos^n x \, dx = \frac{\sin x \cos^{n-1} x}{n} + \frac{n-1}{n} \int \cos^{n-2} x \, dx$
67.  $\int \tan^n x \, dx = \frac{\tan^{n-1} x}{n-1} - \int \tan^{n-2} x \, dx$
68.  $\int \cot^n x \, dx = -\frac{\cot^{n-1} x}{n-1} - \int \cot^{n-2} x \, dx$
69.  $\int \frac{dx}{\sin^n x} = -\frac{\cos x}{(n-1) \sin^{n-1} x} + \frac{n-2}{n-1} \int \frac{dx}{\sin^{n-2} x}$
70.  $\int \frac{dx}{\cos^n x} = \frac{\sin x}{(n-1) \cos^{n-1} x} + \frac{n-2}{n-1} \int \frac{dx}{\cos^{n-2} x}$
- 71.\*  $\int \sin^p x \cos^q x \, dx = \frac{\sin^{p+1} x \cos^{q-1} x}{p+q} + \frac{q-1}{p+q} \int \sin^p x \cos^{q-2} x \, dx$   
 $= -\frac{\sin^{p-1} x \cos^{q+1} x}{p+q} + \frac{p-1}{p+q} \int \sin^{p-2} x \cos^q x \, dx$
- 72.\*  $\int \sin^{-p} x \cos^q x \, dx = -\frac{\sin^{-p+1} x \cos^{q+1} x}{p-1} + \frac{p-q-2}{p-1} \int \sin^{-p+2} x \cos^q x \, dx$
- 73.\*  $\int \sin^p x \cos^{-q} x \, dx = \frac{\sin^{p+1} x \cos^{-q+1} x}{q-1} + \frac{q-p-2}{q-1} \int \sin^p x \cos^{-q+2} x \, dx$
74.  $\int \frac{dx}{a + b \cos x} = \frac{2}{\sqrt{a^2 - b^2}} \tan^{-1} \left( \sqrt{\frac{a-b}{a+b}} \tan \frac{1}{2}x \right) + C, \text{ when } a^2 > b^2$   
 $= \frac{1}{\sqrt{b^2 - a^2}} \ln \frac{b + a \cos x + \sin x \sqrt{b^2 - a^2}}{a + b \cos x} + C$   
 $= \frac{2}{\sqrt{b^2 - a^2}} \tanh^{-1} \left( \sqrt{\frac{b-a}{b+a}} \tan \frac{1}{2}x \right) + C \quad \left. \vphantom{\int \frac{dx}{a + b \cos x}} \right\} [a^2 < b^2]$
75.  $\int \frac{\cos x \, dx}{a + b \cos x} = \frac{x}{b} - \frac{a}{b} \int \frac{dx}{a + b \cos x} + C$
- 

\* If  $n$ ,  $p$ , or  $q$  is an odd number, substitute  $\cos x = z$  or  $\sin x = z$

TABLE 2.24 Integrals (Continued)

| Transcendental functions (continued) |                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 76.                                  | $\int \frac{\sin x \, dx}{a + b \cos x} = -\frac{1}{b} \ln (a + b \cos x) + C$                                                                                                                                                                                                                                                    |

2.2.2 Surface Areas and Volumes\*

Let  $a$ ,  $b$ ,  $c$ ,  $d$ , and  $s$  denote lengths,  $A$  denote areas, and  $V$  denote volumes.

*Triangle.*  $A = bh/2$ , where  $b$  denotes the base and  $h$  the altitude.

*Rectangle.*  $A = ab$ , where  $a$  and  $b$  denote the lengths of the sides.

*Parallelogram* (opposite sides parallel).  $A = ah = ab \sin \theta$ , where  $a$  and  $b$  denote the sides,  $h$  the altitude, and  $\theta$  the angle between the sides.

*Trapezoid* (four sides, two parallel).  $A = \frac{1}{2}h(a + b)$ , where  $a$  and  $b$  are the sides and  $h$  the altitude.

Regular Polygon of  $n$  Sides (Fig. 2.1)

$$A = \frac{1}{4} na^2 \cot \frac{180^\circ}{n} \quad \text{where } a \text{ is length of side}$$

$$R = \frac{a}{2} \csc \frac{180^\circ}{n} \quad \text{where } R \text{ is radius of circumscribed circle}$$

$$r = \frac{a}{2} \cot \frac{180^\circ}{n} \quad \text{where } r \text{ is radius of inscribed circle}$$

$$\alpha = \frac{360^\circ}{n} = \frac{2\pi}{n} \text{ radians}$$

$$\beta = \left( \frac{n-2}{n} \right) \cdot 180^\circ = \left( \frac{n-2}{n} \right) \pi \text{ radians} \quad \text{where } \alpha \text{ and } \beta \text{ are the angles indicated in Fig. 2.1}$$

$$a = 2r \tan \frac{\alpha}{2} = 2R \sin \frac{\alpha}{2}$$

Circle (Fig. 2.2). Let

$C$  = circumference       $S$  = length of arc subtended by  $\theta$

$R$  = radius       $l$  = chord subtended by arc  $S$

$D$  = diameter       $h$  = rise

$A$  = area       $\theta$  = central angle in radians

$$C = 2\pi R = \pi D \quad \pi = 3.14159 \dots$$

$$S = R\theta = \frac{1}{2}D\theta = D \cos^{-1} \frac{d}{R}$$

$$l = 2\sqrt{R^2 - d^2} = 2R \sin \frac{\theta}{2} = 2d \tan \frac{\theta}{2}$$

$$d = \frac{1}{2}\sqrt{4R^2 - l^2} = R \cos \frac{\theta}{2} = \frac{1}{2}l \cot \frac{\theta}{2}$$

$$h = R - d$$

$$\theta = \frac{S}{R} = \frac{2S}{D} = 2 \cos^{-1} \frac{d}{R} = 2 \tan^{-1} \frac{l}{2d} = 2 \sin^{-1} \frac{l}{D}$$

$$A (\text{circle}) = \pi R^2 = \frac{1}{4}\pi D^2$$

$$A (\text{sector}) = \frac{1}{2}Rs = \frac{1}{2}R^2\theta$$

$$A (\text{segment}) = A (\text{sector}) - A (\text{triangle}) = \frac{1}{2}R^2 (\theta - \sin \theta)$$

$$= R^2 \cos^{-1} \frac{R-h}{R} - (R-h)\sqrt{2Rh-h^2}$$

FIGURE 2.1

FIGURE 2.2

Perimeter of  $n$ -sided regular polygon inscribed in a circle  $= 2nR \sin \frac{\pi}{n}$

$$\text{Area of inscribed polygon} = \frac{1}{2}nR^2 \sin \frac{2\pi}{n}$$

Perimeter of  $n$ -sided regular polygon circumscribed about a circle  $= 2nR \tan \frac{\pi}{n}$

$$\text{Area of circumscribed polygon} = nR^2 \tan \frac{\pi}{n}$$

Radius of circle inscribed in a triangle of sides  $a$ ,  $b$ , and  $c$  is

$$r = \sqrt{\frac{(s-a)(s-b)(s-c)}{s}} \quad s = \frac{1}{2}(a+b+c)$$

Radius of circle circumscribed about a triangle is

$$R = \frac{abc}{4\sqrt{s(s-a)(s-b)(s-c)}}$$

*Ellipse* (Fig. 2.3).  $A = \pi ab$ , where  $a$  and  $b$  are lengths of semimajor and semiminor axes, respectively.

*Parabola* (Fig. 2.4)

$$A = \frac{2ld}{3}$$

$$\text{Height of } d_1 = \frac{d}{l^2} (l^2 - l_1^2)$$

$$\text{Width of } l_1 = l \sqrt{\frac{d-d_1}{d}}$$

$$\text{Length of arc} = l \left[ 1 + \frac{2}{3} \left( \frac{2d}{l} \right)^2 - \frac{2}{5} \left( \frac{2d}{l} \right)^4 + \cdots \right]$$

FIGURE 2.3

FIGURE 2.4

*Area by Approximation* (Fig. 2.5). If  $y_0, y_1, y_2, \dots, y_n$  are the length of a series of equally spaced parallel chords, and if  $h$  is their distance apart, the area enclosed by the boundary is given approximately by any one of the following formulae:

$$A_T = h[\frac{1}{2}(y_0 + y_n) + y_1 + y_2 + \cdots + y_{n-1}] \quad (\text{Trapezoidal Rule})$$

FIGURE 2.5

$A_D = h[0.4(y_0 + y_n) + 1.1(y_1 + y_{n-1}) + y_2 + y_3 + \cdots + y_{n-2}]$  (Durand's Rule)

$A_S = \frac{1}{3}h[(y_0 + y_n) + 4(y_1 + y_3 + \cdots + y_{n-1}) + 2(y_2 + y_4 + \cdots + y_{n-2})]$   
( $n$  even, Simpson's Rule)

In general,  $A_S$  gives the most accurate approximation.  
The greater the value of  $n$ , the greater the accuracy of approximation.

*Cube.*  $V = a^3$ ;  $d = a\sqrt{2}$ ; total surface area =  $6a^2$ , where  $a$  is length of side and  $d$  is length of diagonal.

*Rectangular Parallelopiped.*  $V = abc$ ;  $d = \sqrt{a^2 + b^2 + c^2}$ ; total surface area =  $2(ab + bc + ca)$ , where  $a$ ,  $b$ , and  $c$  are the lengths of the sides and  $d$  is length of diagonal.

*Prism or Cylinder*

$V = (\text{area of base}) \cdot (\text{altitude})$

Lateral area = (perimeter of right section)  $\cdot$  (lateral edge)

*Pyramid or Cone*

$V = \frac{1}{3}(\text{area of base}) \cdot (\text{altitude})$

Lateral area of regular pyramid =  $\frac{1}{2}(\text{perimeter of base}) \cdot (\text{slant height})$

*Frustum of Pyramid or Cone.*  $V = \frac{1}{3}(A_1 + A_2 + \sqrt{A_1 \cdot A_2})h$ , where  $h$  is the altitude and  $A_1$  and  $A_2$  are the areas of the bases.

Lateral area of a regular figure =  $\frac{1}{2}(\text{sum of perimeters of base}) \cdot (\text{slant height})$

*Prismoid*

$V = \frac{h}{6} (A_1 + A_2 + 4A_3)$

where  $h$  = altitude,  $A_1$  and  $A_2$  are the areas of the bases, and  $A_3$  is the area of the midsection parallel to bases.

*Area of Surface and Volume of Regular Polyhedra of Edge  $l$*

| Name              | Type of surface          | Area of surface | Volume       |
|-------------------|--------------------------|-----------------|--------------|
| Tetrahedron       | 4 equilateral triangles  | $1.73205l^2$    | $0.11785l^3$ |
| Hexahedron (cube) | 6 squares                | $6.00000l^2$    | $1.00000l^3$ |
| Octahedron        | 8 equilateral triangles  | $3.46410l^2$    | $0.47140l^3$ |
| Dodecahedron      | 12 pentagons             | $20.64578l^2$   | $7.66312l^3$ |
| Icosahedron       | 20 equilateral triangles | $8.66025l^2$    | $2.18170l^3$ |

*Sphere (Fig. 2.6)*

$A \text{ (sphere)} = 4\pi R^2 = \pi D^2$

$A \text{ (zone)} = 2\pi Rh_1 = \pi Dh_1$

$V \text{ (sphere)} = \frac{4}{3}\pi R^3 = \frac{1}{8}\pi D^3$

$$V (\text{spherical sector}) = \frac{2}{3}\pi R^2 h_1 = \frac{1}{6}\pi D^2 h_1$$

$$V (\text{spherical segment of one base}) = \frac{1}{6}\pi h_3 (3r_3^2 + h_3^2)$$

$$V (\text{spherical segment of two bases}) = \frac{1}{6}\pi h_2 (3r_3^2 + 3r_2^2 + h_2^2)$$

$$A (\text{lune}) = 2R^2 \theta \quad \text{where } \theta \text{ is angle in radians of lune}$$

*Ellipsoid.*  $V = \frac{4}{3}\pi abc$ , where  $a$ ,  $b$ , and  $c$  are the lengths of the semiaxes.

*Torus* (Fig. 2.7)

$$V = 2\pi^2 R r^2$$

$$\text{Area of surface} = S = 4\pi^2 R r$$

## 2.2.3 Trigonometric Functions of an Angle $\alpha$

Let  $x$  be any angle whose initial side lies on the positive  $x$  axis and whose vertex is at the origin, and  $(x, y)$  be any point on the terminal side of the angle. ( $x$  is positive if measured along  $OX$  to the right, from the  $y$  axis; and negative, if measured along  $OX'$  to the left from the  $y$  axis. Likewise,  $y$  is positive if measured parallel to  $OY$ , and negative if measured parallel to  $OY'$ .) Let  $r$  be the positive distance from the origin to the point. The trigonometric functions of an angle are defined as follows:

$$\text{sine } \alpha = \sin \alpha = \frac{y}{r}$$

$$\text{cosine } \alpha = \cos \alpha = \frac{x}{r}$$

$$\text{tangent } \alpha = \tan \alpha = \frac{y}{x}$$

$$\text{cotangent } \alpha = \text{ctn } \alpha = \cot \alpha = \frac{x}{y}$$

$$\text{secant } \alpha = \sec \alpha = \frac{r}{x}$$

$$\text{cosecant } \alpha = \csc \alpha = \frac{r}{y}$$

$$\text{exsecant } \alpha = \text{exsec } \alpha = \sec \alpha - 1$$

$$\text{versine } \alpha = \text{vers } \alpha = 1 - \cos \alpha$$

$$\text{coversine } \alpha = \text{covers } \alpha = 1 - \sin \alpha$$

$$\text{haversine } \alpha = \text{hav } \alpha = \frac{1}{2} \text{vers } \alpha$$

### 2.2.3.2 Relations between the Functions of a Single Angle\*

$$\sin^2 x + \cos^2 x = 1$$

$$\tan x = \frac{\sin x}{\cos x}$$

$$\cot x = \frac{1}{\tan x} = \frac{\cos x}{\sin x}$$

$$1 + \tan^2 x = \sec^2 x = \frac{1}{\cos^2 x}$$

$$1 + \cot^2 x = \csc^2 x = \frac{1}{\sin^2 x}$$

FIGURE 2.9

$$\sin x = \sqrt{1 - \cos^2 x} = \frac{\tan x}{\sqrt{1 + \tan^2 x}} = \frac{1}{\sqrt{1 + \cot^2 x}}$$

$$\cos x = \sqrt{1 - \sin^2 x} = \frac{1}{\sqrt{1 + \tan^2 x}} = \frac{\cot x}{\sqrt{1 + \cot^2 x}}$$

**2.2.3.3 Functions of Negative Angles.**  $\sin(-x) = -\sin x$ ;  $\cos(-x) = \cos x$ ;  $\tan(-x) = -\tan x$ .

### 2.2.3.4 Functions of the Sum and Difference of Two Angles

$$\sin(x + y) = \sin x \cos y + \cos x \sin y$$

$$\cos(x + y) = \cos x \cos y - \sin x \sin y$$

$$\tan(x + y) = \frac{\tan x + \tan y}{1 - \tan x \tan y}$$

$$\cot(x + y) = \frac{\cot x \cot y - 1}{\cot x + \cot y}$$

$$\sin(x - y) = \sin x \cos y - \cos x \sin y$$

\* From Baumeister and Marks, *Standard Handbook for Mechanical Engineers*, 7th ed., McGraw-Hill Book Company, New York (1967); by permission.

$$\cos(x - y) = \cos x \cos y + \sin x \sin y$$

$$\tan(x - y) = \frac{\tan x - \tan y}{1 + \tan x \tan y}$$

$$\cot(x - y) = \frac{\cot x \cot y + 1}{\cot y - \cot x}$$

$$\sin x + \sin y = 2 \sin \frac{1}{2}(x + y) \cos \frac{1}{2}(x - y)$$

$$\sin x - \sin y = 2 \cos \frac{1}{2}(x + y) \sin \frac{1}{2}(x - y)$$

$$\cos x + \cos y = 2 \cos \frac{1}{2}(x + y) \cos \frac{1}{2}(x - y)$$

$$\cos x - \cos y = -2 \sin \frac{1}{2}(x + y) \sin \frac{1}{2}(x - y)$$

$$\tan x + \tan y = \frac{\sin(x + y)}{\cos x \cos y} \quad \cot x + \cot y = \frac{\sin(x + y)}{\sin x \sin y}$$

$$\tan x - \tan y = \frac{\sin(x - y)}{\cos x \cos y} \quad \cot x - \cot y = \frac{\sin(y - x)}{\sin x \sin y}$$

$$\sin^2 x - \sin^2 y = \cos^2 y - \cos^2 x = \sin(x + y) \sin(x - y)$$

$$\cos^2 x - \sin^2 y = \cos^2 y - \sin^2 x = \cos(x + y) \cos(x - y)$$

$$\sin(45^\circ + x) = \cos(45^\circ - x) \quad \tan(45^\circ + x) = \cot(45^\circ - x)$$

$$\sin(45^\circ - x) = \cos(45^\circ + x) \quad \tan(45^\circ - x) = \cot(45^\circ + x)$$

In the following transformations,  $a$  and  $b$  are supposed to be positive,  $c = \sqrt{a^2 + b^2}$ ,  $A =$  the positive acute angle for which  $B = b/a$ :

$$a \cos x + b \sin x = c \sin(A + x) = c \cos(B - x)$$

$$a \cos x - b \sin x = c \sin(A - x) = c \cos(B + x)$$

## 2.2.4 Expansion in Series\*

The range of values of  $x$  for which each of the series is convergent is stated at the right of the series.

### 2.2.4.1 Exponential and Logarithmic Series

$$e^x = 1 + \frac{x}{1!} + \frac{x^2}{2!} + \frac{x^3}{3!} + \frac{x^4}{4!} + \cdots \quad (-\infty < x < +\infty)$$

$$a^x = e^{mx} = 1 + \frac{m}{1!}x + \frac{m^2}{2!}x^2 + \frac{m^3}{3!}x^3 + \cdots \quad (a > 0, -\infty < x < +\infty)$$

where  $m = \ln a = 2.3026 \log_{10} a$ .

\* From Baumeister and Marks, *Standard Handbook for Mechanical Engineers*, 7th ed., McGraw-Hill Book Company, New York (1967); by permission.

$$\ln(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \frac{x^5}{5} \cdots \quad (-1 < x < +1)$$

$$\ln(1-x) = -x - \frac{x^2}{2} - \frac{x^3}{3} - \frac{x^4}{4} - \frac{x^5}{5} - \cdots \quad (-1 < x < +1)$$

$$\ln\left(\frac{1+x}{1-x}\right) = 2\left(x + \frac{x^3}{3} + \frac{x^5}{5} + \frac{x^7}{7} + \cdots\right) \quad (-1 < x < +1)$$

$$\ln\left(\frac{x+1}{x-1}\right) = 2\left(\frac{1}{x} + \frac{1}{3x^3} + \frac{1}{5x^5} + \frac{1}{7x^7} + \cdots\right) \quad (x < -1 \text{ or } +1 < x)$$

$$\ln x = 2\left[\frac{x-1}{x+1} + \frac{1}{3}\left(\frac{x-1}{x+1}\right)^3 + \frac{1}{5}\left(\frac{x-1}{x+1}\right)^5 + \cdots\right] \quad (0 < x < \infty)$$

$$\ln(a+x) = \ln a + 2\left[\frac{x}{2a+x} + \frac{1}{3}\left(\frac{x}{2a+x}\right)^3 + \frac{1}{5}\left(\frac{x}{2a+x}\right)^5 + \cdots\right] \\ (0 < a < +\infty, -a < x < +\infty)$$

*Series for the Trigonometric Functions.* In the following formulas, *all angles must be expressed in radians*. If  $D$  = the number of degrees in the angle, and  $x$  = its radian measure, then  $x = 0.017453D$ .

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \cdots \quad (-\infty < x < +\infty)$$

$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \frac{x^8}{8!} - \cdots \quad (-\infty < x < +\infty)$$

$$\tan x = x + \frac{x^3}{3} + \frac{2x^5}{15} + \frac{17x^7}{315} + \frac{62x^9}{2835} + \cdots \quad \left(-\frac{\pi}{2} < x < +\frac{\pi}{2}\right)$$

$$\cot x = \frac{1}{x} - \frac{x}{3} - \frac{x^3}{45} - \frac{2x^5}{945} - \frac{x^7}{4725} - \cdots \quad (-\pi < x < +\pi)$$

$$\sin^{-1} y = y + \frac{y^3}{6} + \frac{3y^5}{40} + \frac{5y^7}{112} + \cdots \quad (-1 \leq y \leq +1)$$

$$\tan^{-1} y = y - \frac{y^3}{3} + \frac{y^5}{5} - \frac{y^7}{7} + \cdots \quad (-1 \leq y \leq +1)$$

$$\cos^{-1} y = \frac{1}{2}\pi - \sin^{-1} y \quad \cot^{-1} y = \frac{1}{2}\pi - \tan^{-1} y$$

*Reversing a Series.* If  $y = x + bx^2 + cx^3 + dx^4 + ex^5 + \cdots$ , then  $x = y - by^2 + (2b^2 - c)y^3 - (5b^3 - 5bc + d)y^4 + (14b^4 - 21b^2c + 6bd + 3c^2 - e)y^5 + \cdots$ , provided the latter series is convergent.

*Fourier's Series.* Let  $f(x)$  be a function which is finite in the interval from  $x = -c$  to  $x = +c$  and whose graph has finite arc length in that interval.\* Then, for any value of  $x$  between  $-c$  and  $c$ ,

\* If  $x = x_0$  is a point of discontinuity,  $f(x_0)$  is to be defined as  $\frac{1}{2}[f_1(x_0) + f_2(x_0)]$ , where  $f_1(x_0)$  is the limit of  $f(x)$  when  $x$  approaches  $x_0$  from below, and  $f_2(x_0)$  is the limit of  $f(x)$  when  $x$  approaches  $x_0$  from above.

$$f(x) = \frac{1}{2}a_0 + a_1 \cos \frac{\pi x}{c} + a_2 \cos \frac{2\pi x}{c} + a_3 \cos \frac{3\pi x}{c} + \cdots$$

$$+ b_1 \sin \frac{\pi x}{c} + b_2 \sin \frac{2\pi x}{c} + b_3 \sin \frac{3\pi x}{c} + \cdots$$

where the constant coefficients are determined as follows:

$$a_n = \frac{1}{c} \int_{-c}^c f(t) \cos \frac{n\pi t}{c} dt$$

$$b_n = \frac{1}{c} \int_{-c}^c f(t) \sin \frac{n\pi t}{c} dt$$

In case the curve  $y = f(x)$  is symmetrical with respect to the origin, the  $a$ 's are all zero, and the series is a sine series. In case the curve is symmetrical with respect to the  $y$  axis, the  $b$ 's are all zero, and a cosine series results. (In this case, the series will be valid not only for values of  $x$  between  $-c$  and  $c$ , but also for  $x = -c$  and  $x = c$ .) A Fourier series can always be integrated term by term; but the result of differentiating term by term may not be a convergent series.

TABLE 2.25 Some Constants

| Constant                                    | Number                    | Log <sub>10</sub> of Number    |

2.3 STATISTICS IN CHEMICAL ANALYSIS

2.3.1 Introduction

Each observation in any branch of scientific investigation is inaccurate to some degree. Often the accurate value for the concentration of some particular constituent in the analyte cannot be determined. However, it is reasonable to assume the accurate value exists, and it is important to estimate the limits between which this value lies. It must be understood that the statistical approach is concerned with the appraisal of experimental design and data. Statistical techniques can neither detect nor evaluate constant errors (bias); the detection and elimination of inaccuracy are analytical problems. Nevertheless, statistical techniques can assist considerably in determining whether or not inaccuracies exist and in indicating when procedural modifications have reduced them.

By proper design of experiments, guided by a statistical approach, the effects of experimental variables may be found more efficiently than by the traditional approach of holding all variables constant but one and systematically investigating each variable in turn. Trends in data may be sought to track down nonrandom sources of error.

### 2.3.2 Errors in Quantitative Analysis

Two broad classes of errors may be recognized. The first class, *determinate* or *systematic* errors, is composed of errors that can be assigned to definite causes, even though the cause may not have been located. Such errors are characterized by being unidirectional. The magnitude may be constant from sample to sample, proportional to sample size, or variable in a more complex way. An example is the error caused by weighing a hygroscopic sample. This error is always positive in sign; it increases with sample size but varies depending on the time required for weighing, with humidity and temperature. An example of a negative systematic error is that caused by solubility losses of a precipitate.

The second class, *indeterminate* or *random* errors, is brought about by the effects of uncontrolled variables. Truly random errors are as likely to cause high as low results, and a small random error is much more probable than a large one. By making the observation coarse enough, random errors would cease to exist. Every observation would give the same result, but the result would be less precise than the average of a number of finer observations with random scatter.

The *precision* of a result is its reproducibility; the *accuracy* is its nearness to the truth. A systematic error causes a loss of accuracy, and it may or may not impair the precision depending upon whether the error is constant or variable. Random errors cause a lowering of reproducibility, but by making sufficient observations it is possible to overcome the scatter within limits so that the accuracy may not necessarily be affected. Statistical treatment can properly be applied only to random errors.

### 2.3.3 Representation of Sets of Data

Raw data are collected observations that have not been organized numerically. An *average* is a value that is typical or representative of a set of data. Several averages can be defined, the most common being the arithmetic mean (or briefly, the mean), the median, the mode, and the geometric mean.

The *mean* of a set of  $N$  numbers,  $x_1, x_2, x_3, \dots, x_N$ , is denoted by  $\bar{x}$  and is defined as:

$$\bar{x} = \frac{x_1 + x_2 + x_3 + \dots + x_N}{N} \quad (2.4)$$

It is an estimation of the unknown true value  $\mu$  of an infinite population. We can also define the *sample variance*  $s^2$  as follows:

$$s^2 = \frac{\sum_{i=1}^N (x_i - \bar{x})^2}{N - 1} \quad (2.5)$$

The values of  $\bar{x}$  and  $s^2$  vary from sample set to sample set. However, as  $N$  increases, they may be expected to become more and more stable. Their limiting values, for very large  $N$ , are numbers characteristic of the frequency distribution, and are referred to as the *population mean* and the *population variance*, respectively.

The *median* of a set of numbers arranged in order of magnitude is the middle value or the arithmetic mean of the two middle values. The median allows inclusion of all data in a set without undue influence from outlying values; it is preferable to the mean for small sets of data.

The *mode* of a set of numbers is that value which occurs with the greatest frequency (the most common value). The mode may not exist, and even if it does exist it may not be unique. The empirical relation that exists between the mean, the mode, and the median for unimodal frequency curves which are moderately asymmetrical is:

$$\text{Mean} - \text{mode} = 3(\text{mean} - \text{median}) \quad (2.6)$$

The *geometric mean* of a set of  $N$  numbers is the  $N$ th root of the product of the numbers:

$$\sqrt[N]{x_1 x_2 x_3 \dots x_N} \quad (2.7)$$

The *root mean square* (RMS) or quadratic mean of a set of numbers is defined by:

$$\text{RMS} = \sqrt{\bar{x}^2} = \sqrt{\sum_{i=1}^N x_i^2 / N} \quad (2.8)$$

### 2.3.4 The Normal Distribution of Measurements

The normal distribution of measurements (or the normal law of error) is the fundamental starting point for analysis of data. When a large number of measurements are made, the individual measurements are not all identical and equal to the accepted value  $\mu$ , which is the mean of an infinite population or universe of data, but are scattered about  $\mu$ , owing to random error. If the magnitude of any single measurement is the abscissa and the relative frequencies (i.e., the probability) of occurrence of different-sized measurements are the ordinate, the smooth curve drawn through the points (Fig. 2.10) is the *normal* or *Gaussian distribution curve* (also the *error curve* or *probability curve*). The term *error curve* arises when one considers the distribution of errors ( $x - \mu$ ) about the true value.

FIGURE 2.10 The Normal Distribution Curve.

The breadth or spread of the curve indicates the precision of the measurements and is determined by and related to the standard deviation, a relationship that is expressed in the equation for the normal curve (which is continuous and infinite in extent):

$$Y = \frac{1}{\sigma\sqrt{2\pi}} \exp \left[ -\frac{1}{2} \left( \frac{x - \mu}{\sigma} \right)^2 \right] \quad (2.9)$$

where  $\sigma$  is the standard deviation of the infinite population. The population mean  $\mu$  expresses the magnitude of the quantity being measured. In a sense,  $\sigma$  measures the width of the distribution, and thereby also expresses the scatter or dispersion of replicate analytical results. When  $(x - \mu)/\sigma$  is replaced by the standardized variable  $z$ , then:

$$Y = \frac{1}{\sqrt{2\pi}} e^{-(1/2)z^2} \quad (2.10)$$

The standardized variable (the  $z$  statistic) requires only the probability level to be specified. It measures the deviation from the population mean in units of standard deviation.  $Y$  is 0.399 for the most probable value,  $\mu$ . In the absence of any other information, the normal distribution is assumed to apply whenever repetitive measurements are made on a sample, or a similar measurement is made on different samples.

Table 2.26a lists the height of an ordinate ( $Y$ ) as a distance  $z$  from the mean, and Table 2.26b the area under the normal curve at a distance  $z$  from the mean, expressed as fractions of the total area, 1.000. Returning to Fig. 2.10, we note that 68.27% of the area of the normal distribution curve lies within 1 standard deviation of the center or mean value. Therefore, 31.73% lies outside those limits and 15.86% on each side. Ninety-five percent (actually 95.43%) of the area lies within 2 standard deviations, and 99.73% lies within 3 standard deviations of the mean. Often the last two areas are stated slightly different; viz. 95% of the area lies within  $1.96\sigma$  (approximately  $2\sigma$ ) and 99% lies within approximately  $2.5\sigma$ . The mean falls at exactly the 50% point for symmetric normal distributions.

**Example 5** The true value of a quantity is 30.00, and  $\sigma$  for the method of measurement is 0.30. What is the probability that a single measurement will have a deviation from the mean greater than 0.45; that is, what percentage of results will fall outside the range  $30.00 \pm 0.45$ ?

$$z = \frac{x - \mu}{\sigma} = \frac{0.45}{0.30} = 1.5$$

From Table 2.26b the area under the normal curve from  $-1.5\sigma$  to  $+1.5\sigma$  is 0.866, meaning that 86.6% of the measurements will fall within the range  $30.00 \pm 0.45$  and 13.4% will lie outside this range. Half of these measurements, 6.7%, will be less than 29.55; and a similar percentage will exceed 30.45. In actuality the uncertainty in  $z$  is about 1 in 15; therefore, the value of  $z$  could lie between 1.4 and 1.6; the corresponding areas under the curve could lie between 84% and 89%.

**Example 6** If the mean value of 500 determinations is 151 and  $\sigma = 15$ , how many results lie between 120 and 155 (actually any value between 119.5 and 155.5)?

$$z = \frac{119.5 - 151}{15} = -2.10 \quad \text{Area: 0.482}$$

$$z = \frac{155.5 - 151}{15} = 0.30 \quad 0.118$$

Total area: 0.600

$$500(0.600) = 300 \text{ results}$$

2.3.5 Standard Deviation as a Measure of Dispersion

Several ways may be used to characterize the spread or dispersion in the original data. The *range* is the difference between the largest value and the smallest value in a set of observations. However, almost always the most efficient quantity for characterizing variability is the *standard deviation* (also called the *root mean square*).

The standard deviation is the square root of the average squared differences between the individual observations and the population mean:

$$\sigma = \sqrt{\frac{\sum_{i=1}^N (x_i - \mu)^2}{N}}$$

(2.11)

The standard deviation  $\sigma$  may be estimated by calculating the standard deviation  $s$  drawn from a small sample set as follows:

$$s = \sqrt{\frac{\sum_{i=1}^N (x_i - \bar{x})^2}{N}} \quad \text{or} \quad s = \sqrt{\frac{x_1^2 + x_2^2 + \cdots - [(x_1 + x_2 + \cdots)^2]/N}{N - 1}} \quad (2.12)$$

where  $x_i - \bar{x}$  represents the deviation of each number in the array from the arithmetic mean. Since two pieces of information, namely  $s$  and  $\bar{x}$ , have been extracted from the data, we are left with  $N - 1$  *degrees of freedom* (df); that is, independent data points available for measurement of precision. If a relatively large sample of data corresponding to  $N > 30$  is available, its mean can be taken as a measure of  $\mu$ , and  $s$  as equal to  $\sigma$ .

So basic is the notion of a statistical *estimate* of a physical parameter that statisticians use Greek letters for the *parameters* and Latin letters for the estimates. For many purposes, one uses the *variance*, which for the sample is  $s^2$  and for the entire populations is  $\sigma^2$ . The variance  $s^2$  of a finite sample is an unbiased estimate of  $\sigma^2$ , whereas the standard deviation  $s$  is not an unbiased estimate of  $\sigma$ .

Because the standard deviation  $\sigma$  for the universe is a characteristic of the measuring procedure, it is possible to get a good estimate not only from a long series of repeated analyses of the same sample, but also by taking together several short series measured with slightly different samples of the same type. When a series of observations can be logically arranged into  $k$  subgroups, the variance is calculated by summing the squares of the deviations for each subgroup, and then adding all the  $k$  sums and dividing by  $N - k$  because one degree of freedom is lost in each subgroup. It is not required that the number of repeated analyses in the different groups be the same. For two groups of observations consisting of  $N_A$  and  $N_B$  members of standard deviations  $s_A$  and  $s_B$ , respectively, the variance is given by:

$$s^2 = \frac{(N_A - 1)s_A^2 + (N_B - 1)s_B^2}{N_A + N_B - 2} \quad (2.13)$$

Another measure of dispersion is the *coefficient of variation*, which is merely the standard deviation expressed as a fraction of the arithmetic mean, viz.,  $s/\bar{x}$ . It is useful mainly to show whether the relative or the absolute spread of values is constant as the values are changed.

### 2.3.6 Student's Distribution or $t$ Test

In the next several sections, the theoretical distributions and tests of significance will be examined beginning with Student's distribution or  $t$  test. If the data contained only random (or chance) errors, the cumulative estimates  $\bar{x}$  and  $s$  would gradually approach the limits  $\mu$  and  $\sigma$ . The distribution of results would be normally distributed with mean  $\mu$  and standard deviation  $\sigma$ . Were the true mean of the infinite population known, it would also have some symmetrical type of distribution centered around  $\mu$ . However, it would be expected that the dispersion or spread of this dispersion about the mean would depend on the sample size.

The standard deviation of the distribution of means equals  $\sigma/N^{1/2}$ . Since  $\sigma$  is not usually known, its approximation for a finite number of measurements is overcome by the Student  $t$  test. It is a measure of error between  $\mu$  and  $\bar{x}$ . The Student  $t$  takes into account both the possible variation of the value of  $\bar{x}$  from  $\mu$  on the basis of the expected variance  $\sigma^2/N^{1/2}$  and the reliability of using  $s$  in place of  $\sigma$ . The distribution of the statistic is:

$$\pm t = \frac{\bar{x} - \mu}{s/\sqrt{N}} \quad \text{or} \quad \mu = \bar{x} \pm \frac{ts}{\sqrt{N}} \quad (2.14)$$

The distribution of the  $t$ -statistic  $(\bar{x} - \mu)s$  is symmetrical about zero and is a function of the degrees of freedom. Limits assigned to the distance on either side of  $\mu$  are called *confidence limits*. The percentage probability that  $\mu$  lies within this interval is called the *confidence level*. The *level of significance* or *error probability* ( $100 - \text{confidence level}$  or  $100 - \alpha$ ) is the percent probability that  $\mu$  will lie outside the confidence interval, and represents the chances of being incorrect in stating that  $\mu$  lies within the confidence interval. Values of  $t$  are in Table 2.27 for any desired degrees of freedom and various confidence levels.

An analytical procedure is often tested on materials of known composition. These materials may be pure substances, standard samples, or materials analyzed by some other more accurate method. Repeated determinations on a known material furnish data for both an estimate of the precision and a test for the presence of a constant error in the results. The standard deviation is found from Equation 12 (with the known composition replacing  $\mu$ ). A calculated value for  $t$  (Eq. 14) in excess of the appropriate value in Table 2.27 is interpreted as evidence of the presence of a constant error at the indicated level of significance.

**TABLE 2.27** Percentile Values for Student  $t$  Distribution

| df       | $t_{0.995}$ | $t_{0.99}$ | $t_{0.975}$ | $t_{0.95}$ | $t_{0.90}$ | $t_{0.80}$ | $t_{0.75}$ | $t_{0.70}$ | $t_{0.60}$ | $t_{0.55}$ |
|----------|-------------|------------|-------------|------------|------------|------------|------------|------------|------------|------------|
| 1        | 63.66       | 31.82      | 12.71       | 6.31       | 3.08       | 1.376      | 1.000      | 0.727      | 0.325      | 0.158      |
| 2        | 9.92        | 6.96       | 4.30        | 2.92       | 1.89       | 1.061      | 0.816      | 0.617      | 0.289      | 0.142      |
| 3        | 5.84        | 4.54       | 3.18        | 2.35       | 1.64       | 0.978      | 0.765      | 0.584      | 0.277      | 0.137      |
| 4        | 4.60        | 3.75       | 2.78        | 2.13       | 1.53       | 0.941      | 0.741      | 0.569      | 0.271      | 0.134      |

| 22       | 2.82        | 2.51       | 2.07        | 1.72       | 1.32       | 0.858      | 0.686      | 0.532      | 0.256      | 0.127      |
| 23       | 2.81        | 2.50       | 2.07        | 1.71       | 1.32       | 0.858      | 0.685      | 0.532      | 0.256      | 0.127      |
| 24       | 2.80        | 2.49       | 2.06        | 1.71       | 1.32       | 0.857      | 0.685      | 0.531      | 0.256      | 0.127      |
| 25       | 2.79        | 2.48       | 2.06        | 1.71       | 1.32       | 0.856      | 0.684      | 0.531      | 0.256      | 0.127      |
| 26       | 2.78        | 2.48       | 2.06        | 1.71       | 1.32       | 0.856      | 0.684      | 0.531      | 0.256      | 0.127      |
| 27       | 2.77        | 2.47       | 2.05        | 1.70       | 1.31       | 0.855      | 0.684      | 0.531      | 0.256      | 0.127      |
| 28       | 2.76        | 2.47       | 2.05        | 1.70       | 1.31       | 0.855      | 0.683      | 0.530      | 0.256      | 0.127      |
| 29       | 2.76        | 2.46       | 2.04        | 1.70       | 1.31       | 0.854      | 0.683      | 0.530      | 0.256      | 0.127      |
| 30       | 2.75        | 2.46       | 2.04        | 1.70       | 1.31       | 0.854      | 0.683      | 0.530      | 0.256      | 0.127      |
| 40       | 2.70        | 2.42       | 2.02        | 1.68       | 1.30       | 0.851      | 0.681      | 0.529      | 0.255      | 0.126      |
| 60       | 2.66        | 2.39       | 2.00        | 1.67       | 1.30       | 0.848      | 0.679      | 0.527      | 0.254      | 0.126      |
| 120      | 2.62        | 2.36       | 2.98        | 1.66       | 1.29       | 0.845      | 0.677      | 0.526      | 0.254      | 0.126      |
| $\infty$ | 2.58        | 2.33       | 1.96        | 1.645      | 1.28       | 0.842      | 0.674      | 0.524      | 0.253      | 0.126      |

*Example 7* A new method for the analysis of iron using pure FeO was replicated with five samples giving these results (in % Fe): 76.95, 77.02, 76.90, 77.20, and 77.50. Does a systematic error exist?

From Equation 4,  $\bar{x}$  is 77.11; and from Equation 5,  $s$  is 0.24 for 4 degrees of freedom. Because  $\sigma$  is not known, the Student  $t_{0.975}$  (2.78 for 4 degrees of freedom) is used to calculate the confidence interval at the 95% probability level.

$$\mu = \bar{x} \pm \frac{ts}{\sqrt{N}} = 77.11 \pm \frac{(2.78)(0.24)}{\sqrt{5}} = 77.11 \pm 0.30$$

We used a two-tailed test. Upon rereading the problem, we realize that this was pure FeO whose iron content was 77.60% so that  $\mu = 77.60$  and the confidence interval does not include the known value. Since the FeO was a standard, a one-tailed test should have been used since only random values would be expected to exceed 77.60%. Now the Student  $t$  value of 2.13 (for  $-t_{0.05}$ ) should have been used, and now the confidence interval becomes  $77.11 \pm 0.23$ . A systematic error is presumed to exist.

The  $t$  test can be applied to differences between pairs of observations. Perhaps only a single pair can be performed at one time, or possibly one wishes to compare two methods using samples of differing analytical content. It is still necessary that the two methods possess the same inherent standard deviation. An average difference  $\bar{d}$  calculated, and individual deviations from  $\bar{d}$  are used to evaluate the variance of the differences.

*Example 8* From the following data do the two methods actually give concordant results?

| Sample | Method A | Method B | Difference       |
|--------|----------|----------|------------------|
| 1      | 33.27    | 33.04    | $d_1 = 0.23$     |
| 2      | 51.34    | 50.96    | $d_2 = 0.38$     |
| 3      | 23.91    | 23.77    | $d_3 = 0.14$     |
| 4      | 47.04    | 46.79    | $d_4 = 0.25$     |
|        |          |          | $\bar{d} = 0.25$ |

$$s_d = \frac{\sqrt{\sum (d - \bar{d})^2}}{N - 1} = 0.099$$
$$t = \frac{0.25}{0.099} \sqrt{4 - 1} = 4.30$$

From Table 2.27,  $t_{0.975} = 3.18$  (at 95% probability) and  $t_{0.995} = 5.84$  (at 99% probability). The difference between the two methods is probably significant.

If the  $t$ -value falls short of the formal significance level, this is not to be interpreted as proving the absence of a systematic error. Perhaps the data were insufficient in precision or in number to establish the presence of a constant error. Especially when the calculated value for  $t$  is only slightly short of the tabulated value, some additional data may suffice to build up the evidence for a constant error (or the lack thereof).

Should there be more than one known material, a weighted average of the individual differences ( $\bar{x}$ ) should be taken. The value of  $s$  should be based on the combined estimate from the two or more materials (perhaps different primary standards for bases). Should the materials differ markedly in composition, a plot of the individual constant errors against composition should be made. If the constant error appear to depend upon the composition, they should not be pooled in a weighted average.

The  $t$  test is also used to judge whether a given lot of material conforms to a particular specification. If both plus and minus departures from the known value are to be guarded against, a two-tailed test is involved. If departures in only one direction are undesirable, then the 10% level values for  $t$  are appropriate for the 5% level in *one* direction. Similarly, the 2% level should be used to obtain the 1% level to test the departure from the known value in one direction only; these constitute a one-tailed test. More on this subject will be in the next section.

Sometimes just one determination is available on each of several known materials similar in composition. A single determination by each of two procedures (or two analysts) on a series of material may be used to test for a relative bias between the two methods, as in Example 2.4. Of course, the average difference does not throw any light on which procedure has the larger constant error. It only supplies a test as to whether the two procedures are in disagreement.

### 2.3.7 Hypotheses About Means

Statistical methods are frequently used to give a “yes” or “no” answer to a particular question concerning the significance of data. When performing hypothesis tests on real data, we cannot set an absolute cutoff as to where we can expect to find no values from the population against which we are testing data, but we can set a limit beyond which we consider it very unlikely to find a member of the population. If a measurement is made that does in fact fall outside the specified range, the probability of its happening by chance alone can be rejected; something beyond the randomness of the reference population must be operating. In other words, hypothesis testing is an attempt to determine whether a given measured statistic could have come from some hypothesized population.

In attempting to reach decisions, it is useful to make assumptions or guesses about the populations involved. Such assumptions, which may or may not be true, are called *statistical hypotheses* and in general are statements about the probability distributions of the populations. A common procedure is to set up a *null hypothesis*, denoted by  $H_0$ , which states that there is no significant difference between two sets of data or that a variable exerts no significant effect. Any hypothesis which differs from a null hypothesis is called an *alternative hypothesis*, denoted by  $H_1$ .

Our answer is qualified by a confidence level (or level of significance) indicating the degree of certainty of the answer. Generally confidence levels of 95% and 99% are chosen to express the probability that the answer is correct. These are also denoted as the 0.05 and 0.01 level of significance, respectively. When the hypothesis can be rejected at the 0.05 level of significance, but not at the 0.01 level, we can say that the sample results are probably significant. If, however, the hypothesis is also rejected at the 0.01 level, the results become highly significant.

The abbreviated table on the next page, which gives critical values of  $z$  for both one-tailed and two-tailed tests at various levels of significance, will be found useful for purposes of reference. Critical values of  $z$  for other levels of significance are found by the use of Table 2.26b. For a small number of samples we replace  $z$ , obtained from above or from Table 2.26b, by  $t$  from Table 2.27, and we replace  $\sigma$  by:

$$[\sqrt{N/(N-1)}] s$$

| Level of significance, $\alpha$             | 0.10                 | 0.05                | 0.01               | 0.005              | 0.002              |
|---------------------------------------------|----------------------|---------------------|--------------------|--------------------|--------------------|
| Critical values of $z$ for one-tailed tests | – 1.28<br>or 1.28    | – 1.645<br>or 1.645 | – 2.33<br>or 2.33  | – 2.58<br>or 2.58  | – 2.88<br>or 2.88  |
| Critical values of $z$ for two-tailed tests | – 1.645<br>and 1.645 | – 1.96<br>and 1.96  | – 2.58<br>and 2.58 | – 2.81<br>and 2.81 | – 3.08<br>and 3.08 |

Procedures which enable us to decide whether to accept or reject hypotheses or to determine whether observed samples differ significantly from expected results are called *tests of hypotheses*, *tests of significance*, or *rules of decision*. For example, a set of  $z$  values outside the range – 1.96 to 1.96 (at the 0.05 level of significance for a two-tailed test), constitute what is called the critical region or region of rejection of the hypothesis. The set of  $z$  results inside the range – 1.96 to 1.96 could then be called the region of acceptance of the hypothesis.

*Example 9* In the past a method gave  $\mu = 0.050\%$ . A recent set of 10 results gave  $\bar{x} = 0.053\%$  and  $s = 0.003\%$ . Is everything satisfactory at a level of significance of 0.05? Of 0.01? We wish to decide between the hypotheses:

- $H_0: \mu = 0.050\%$       and the method is working properly, and
- $H_1: \mu \neq 0.050\%$       and the method is not working properly.

A *two-tailed test* is required; that is, both tails on the distribution curve are involved:

$$t = \frac{0.053 - 0.050}{0.003} \sqrt{10 - 1} = -3.00$$

Enter Table 2.27 for nine degrees of freedom under the column headed  $t_{0.975}$  for the 0.05 level of significance, and the column  $t_{0.995}$  for the 0.01 level of significance. At the 0.05 level, accept  $H_0$  if  $t$  lies inside the interval  $-t_{0.975}$  to  $t_{0.975}$ , that is, within – 2.26 and 2.26; reject otherwise. Since  $t = -3.00$ , we reject  $H_0$ . At the 0.01 level of significance, the corresponding interval is – 3.25 to 3.25, which  $t$  lies within, indicating acceptance of  $H_0$ . Because we can reject  $H_0$  at the 0.05 level but not at the 0.01 level of significance, we can say that the sample results are probably significant and that the method is working properly.

Let us digress a moment and consider when a two-tailed test is needed, and what a one-tailed test implies. We “assume” that the measurements can be described by the curve shown in Fig. 2.10. If so, then 95% of the time a sample from the specified population will fall within the indicated range and 5% of the time it will fall outside; 2.5% of the time it is outside on the high side of the range, and 2.5% of the time it is below the low side of the range. Our assumption implies that if  $\mu$  does not equal the hypothesized value, the probability of its being above the hypothesized value is equal to the probability of its being below the hypothesized value.

There will be incidences when the foregoing assumptions for a two-tailed test will not be true. Perhaps some physical situation prevents  $\mu$  from ever being less than the hypothesized value; it can only be equal or greater. No results would ever fall below the low end of the confidence interval; only the upper end of the distribution is operative. Now random samples will exceed the upper bound only 2.5% of the time, not the 5% specified in two-tail testing. Thus, where the possible values are restricted, what was supposed to be a hypothesis test at the 95% confidence level is actually being performed at a 97.5% confidence level. Stated in another way, 95% of the population data lie within the interval below  $\mu + 1.65\sigma$  and 5% lie above. Of course, the opposite situation might also occur and only the lower end of the distribution is operative.

**Example 10** Six samples from a bulk chemical shipment averaged 77.50% active ingredient with  $s = 1.45\%$ . The manufacturer claimed 80.00%. Can this claim be supported?

A one-tailed test is required since the alternative hypothesis states that the population parameter is equal to or less than the hypothesized value.

$$t = \frac{77.50 - 80.00}{1.45} \sqrt{6 - 1} = 3.86$$

Since  $t_{0.95} = -2.01$ , and  $t_{0.99} = -3.36$ , the hypothesis is rejected at both the 0.05 and the 0.01 levels of significance. It is extremely unlikely that the claim is justified.

### 2.3.8 The Chi-square ( $\chi^2$ ) Distribution

The  $\chi^2$  distribution describes the behavior of variances. Actually there is not a single  $\chi^2$  distribution but a whole set of distributions. Each distribution depends upon the number of degrees of freedom (designated variously as  $df$ ,  $d.f.$ , or  $f$ ) in that distribution. Table 2.28 is laid out so that the horizontal axis is labeled with probability levels, while the vertical axis is listed in descending order of increasing number of degrees of freedom. The entries increase both as you read down and across the table. Although Table 2.28 does not display the values for the mid-range of the distributions, at the 50% point of each distribution, the expected value of  $\chi^2$  is equal to the degrees of freedom. Estimates of the variance are uncertain when based only on a few degrees of freedom. With the 10 samples in Example 11, the standard deviation can vary by a large factor purely by random chance alone. Even 31 samples gives a spread of standard deviation of 2.6 at the 95% confidence level.

Understanding the  $\chi^2$  distribution allows us to calculate the expected values of random variables that are normally and independently distributed. In least squares multiple regression, or in calibration work in general, there is a basic assumption that the error in the response variable is random and normally distributed, with a variance that follows a  $\chi^2$  distribution.

Confidence limits for an estimate of the variance may be calculated as follows. For each group of samples a standard deviation is calculated. These estimates of  $\sigma$  possess a distribution called the  $\chi^2$  distribution:

$$\chi^2 = \frac{s^2}{\sigma^2/df} \quad (2.15)$$

The upper and lower confidence limits for the standard deviation are obtained by dividing  $(N - 1)s^2$  by two entries taken from Table 2.28. The estimate of variance at the 90% confidence limits is for use in the entries  $\chi_{0.05}^2$  and  $\chi_{0.95}^2$  (for 5% and 95%) with  $N$  degrees of freedom.

**Example 11** The variance obtained for 10 samples is  $(0.65)^2$ .  $\sigma^2$  is known to be  $(0.75)^2$ . How reliable is  $s^2$  as an estimate of  $\sigma^2$ ?

$$\begin{aligned} \frac{s^2 (N - 1)}{\chi_{0.975}^2} &< \sigma^2 < \frac{s^2 (N - 1)}{\chi_{0.025}^2} \\ \frac{(0.65)^2 (10 - 1)}{19.02} &< \sigma^2 < \frac{(0.65)^2 (10 - 1)}{2.70} \\ 0.20 &< \sigma^2 < 1.43 \end{aligned}$$

Thus, only one time in 40 will  $9s^2/\sigma^2$  be less than 2.70 by chance alone. Similarly, only one time

**TABLE 2.28** Percentile Values for the Chi-square ( $\chi^2$ ) Distribution

| df  | $\chi^2_{0.995}$ | $\chi^2_{0.99}$ | $\chi^2_{0.975}$ | $\chi^2_{0.95}$ | $\chi^2_{0.90}$ | $\chi^2_{0.75}$ | $\chi^2_{0.50}$ | $\chi^2_{0.25}$ | $\chi^2_{0.10}$ | $\chi^2_{0.05}$ | $\chi^2_{0.025}$ | $\chi^2_{0.01}$ | $\chi^2_{0.005}$ |
|-----|------------------|-----------------|------------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|------------------|-----------------|------------------|
| 1   | 7.88             | 6.63            | 5.02             | 3.84            | 2.71            | 1.32            | 0.455           | 0.102           | 0.0158          | 0.0039          | 0.0010           | 0.0002          | 0.0000           |

in 40 will  $9s^2/\sigma^2$  be greater than 19.02. Consequently, it is not unlikely that  $s^2$  is a reliable estimate of  $\sigma^2$ .

Stated differently:

Upper limit:  $\sigma^2 = 9s^2/2.7 = 3.3s^2$

Lower limit:  $\sigma^2 = 9s^2/19.02 = 0.48s^2$

Ten measurements give an estimate of  $\sigma^2$  that may be as much as 3.3 times or only about one-half the true variance.

### 2.3.9 The $F$ Statistic

The  $F$  statistic, along with the  $z$ ,  $t$ , and  $\chi^2$  statistics, constitute the group that are thought of as fundamental statistics. Collectively they describe all the relationships that can exist between means and standard deviations. To perform an  $F$  test, we must first verify the randomness and independence of the errors. If  $\sigma_1^2 = \sigma_2^2$ , then  $s_1^2/s_2^2$  will be distributed properly as the  $F$  statistic. If the calculated  $F$  is outside the confidence interval chosen for that statistic, then this is evidence that  $\sigma_1^2 \neq \sigma_2^2$ .

The  $F$  statistic describes the distribution of the ratios of variances of two sets of samples. It requires three table labels: the probability level and the two degrees of freedom. Since the  $F$  distribution requires a three-dimensional table which is effectively unknown, the  $F$  tables are presented as large sets of two-dimensional tables. The  $F$  distribution in Table 2.29 has the different numbers of degrees of freedom for the denominator variance placed along the vertical axis, while in each table the two horizontal axes represent the numerator degrees of freedom and the probability level. Only two probability levels are given in Table 2.29: the upper 5% points ( $F_{0.95}$ ) and the upper 1% points ( $F_{0.99}$ ). More extensive tables of statistics will list additional probability levels, and they should be consulted when needed.

It is possible to compare the means of two relatively small sets of observations when the variances within the sets can be regarded as the same, as indicated by the  $F$  test. One can consider the distribution involving estimates of the true variance. With  $s_1^2$  determined from a group of  $N_1$  observations and  $s_2^2$  from a second group of  $N_2$  observations, the distribution of the ratio of the sample variances is given by the  $F$  statistic:

$$F = \frac{s_1^2/\sigma_1^2}{s_2^2/\sigma_2^2} \quad (2.16)$$

The larger variance is placed in the numerator. For example, the  $F$  test allows judgment regarding the existence of a significant difference in the precision between two sets of data or between two analysts. The hypothesis assumed is that both variances are indeed alike and a measure of the same  $\sigma$ .

The fact that each sample variance is related to its own population variance means that the sample variance being used for the calculation need not come from the same population. This is a significant departure from the assumptions inherent in the  $z$ ,  $t$ , and  $\chi^2$  statistics.

**Example 12** Suppose Analyst A made five observations and obtained a standard deviation of 0.06, where Analyst B with six observations obtained  $s_B = 0.03$ . The experimental variance ratio is:

$$F = \frac{(0.06)^2}{(0.03)^2} = 4.00$$

From Table 2.28 with four degrees of freedom for A and five degrees of freedom for B, the value of  $F$  would exceed 5.19 five percent of the time. Therefore, the null hypothesis is valid, and comparable skills are exhibited by the two analysts.

As applied in Example 12, the  $F$  test was one-tailed. The  $F$  test may also be applied as a two-tailed test in which the alternative to the null hypothesis is  $\sigma_1^2 \neq \sigma_2^2$ . This doubles the probability that the null hypothesis is invalid and has the effect of changing the confidence level, in the above example, from 95% to 90%.

If improvement in precision is claimed for a set of measurements, the variance for the set against which comparison is being made should be placed in the numerator, regardless of magnitude. An experimental  $F$  smaller than unity indicates that the claim for improved precision cannot be supported. The technique just given for examining whether the precision varies with the two different analytical procedures, also serves to compare the precision with different materials, or with different operators, laboratories, or sets of equipment.

**TABLE 2.29** *F* Distribution  
*Interpolation should be performed using reciprocals of the degrees of freedom.*

| Upper 5% points ( $F_{0.95}$ )     |                                  |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |          |  |

| 25                                 | 7.77                             | 5.57 | 4.68 | 4.18 | 3.86 | 3.63 | 3.46 | 3.32 | 3.22 | 3.13 | 2.99 | 2.85 | 2.70 | 2.62 | 2.53 | 2.45 | 2.36 | 2.27 | 2.17     |  |
| 30                                 | 7.56                             | 5.39 | 4.51 | 4.02 | 3.70 | 3.47 | 3.30 | 3.17 | 3.07 | 2.98 | 2.84 | 2.70 | 2.55 | 2.47 | 2.39 | 2.30 | 2.21 | 2.11 | 2.01     |  |
| 40                                 | 7.31                             | 5.18 | 4.31 | 3.83 | 3.51 | 3.29 | 3.12 | 2.99 | 2.89 | 2.80 | 2.66 | 2.52 | 2.37 | 2.29 | 2.20 | 2.11 | 2.02 | 1.92 | 1.80     |  |
| 60                                 | 7.08                             | 4.98 | 4.13 | 3.65 | 3.34 | 3.12 | 2.95 | 2.82 | 2.72 | 2.63 | 2.50 | 2.35 | 2.20 | 2.12 | 2.03 | 1.94 | 1.84 | 1.73 | 1.60     |  |
| 120                                | 6.85                             | 4.79 | 3.95 | 3.48 | 3.17 | 2.96 | 2.79 | 2.66 | 2.56 | 2.47 | 2.34 | 2.19 | 2.03 | 1.95 | 1.86 | 1.76 | 1.66 | 1.53 | 1.38     |  |
| $\infty$                           | 6.63                             | 4.61 | 3.78 | 3.32 | 3.02 | 2.80 | 2.64 | 2.51 | 2.41 | 2.32 | 2.18 | 2.04 | 1.88 | 1.79 | 1.70 | 1.59 | 1.47 | 1.32 | 1.00     |  |

### 2.3.10 Curve Fitting

Very often in practice a relationship is found (or known) to exist between two or more variables. It is frequently desirable to express this relationship in mathematical form by determining an equation connecting the variables.

The first step is the collection of data showing corresponding values of the variables under consideration. From a scatter diagram, a plot of  $Y$  (ordinate) versus  $X$  (abscissa), it is often possible to visualize a smooth curve approximating the data. For purposes of reference, several types of approximating curves and their equations are listed. All letters other than  $X$  and  $Y$  represent constants.

- |                                                        |                             |
|--------------------------------------------------------|-----------------------------|
| 1. $Y = a_0 + a_1X$                                    | Straight line               |
| 2. $Y = a_0 + a_1X + a_2X^2$                           | Parabola or quadratic curve |
| 3. $Y = a_0 + a_1X + a_2X^2 + a_3X^3$                  | Cubic curve                 |
| 4. $Y = a_0 + a_1X + a_2 + \cdot \cdot \cdot + a_nX^n$ | $n$ th degree curve         |

As other possible equations (among many) used in practice, these may be mentioned:

- |                                                  |                            |
|--------------------------------------------------|----------------------------|
| 5. $Y = (a_0 + a_1X)^{-1}$ or $1/Y = a_0 + a_1X$ | Hyperbola                  |
| 6. $Y = ab^X$ or $\log Y = \log a + (\log b)_X$  | Exponential curve          |
| 7. $Y = aX^b$ or $\log Y = \log a + b \log X$    | Geometric curve            |
| 8. $Y = ab^X + g$                                | Modified exponential curve |
| 9. $Y = aX^n + g$                                | Modified geometric curve   |

When we draw a scatter plot of all  $X$  versus  $Y$  data, we see that some sort of shape can be described by the data points. From the scatter plot we can take a basic guess as to which type of curve will best describe the  $X$ — $Y$  relationship. To aid in the decision process, it is helpful to obtain scatter plots of transformed variables. For example, if a scatter plot of  $\log Y$  versus  $X$  shows a linear relationship, the equation has the form of number 6 above, while if  $\log Y$  versus  $\log X$  shows a linear relationship, the equation has the form of number 7. To facilitate this we frequently employ special graph paper for which one or both scales are calibrated logarithmically. These are referred to as *semilog* or *log-log graph paper*, respectively.

**2.3.10.1 The Least Squares or Best-fit Line.** The simplest type of approximating curve is a straight line, the equation of which can be written as in form number 1 above. It is customary to employ the above definition when  $X$  is the independent variable and  $Y$  is the dependent variable.

To avoid individual judgment in constructing any approximating curve to fit sets of data, it is necessary to agree on a definition of a *best-fit line*. One could construct what would be considered the best-fit line through the plotted pairs of data points. For a given value of  $X_1$ , there will be a difference  $D_1$  between the value  $Y_1$  and the constituent value  $\hat{Y}$  as determined by the calibration model. Since we are assuming that all the errors are in  $Y$ , we are seeking the best-fit line that minimizes the deviations in the  $Y$  direction between the experimental points and the calculated line. This condition will be met when the sum of squares for the differences, called residuals (or the sum of squares due to error),

$$\sum_{i=1}^N (Y_i - \hat{Y}_i)^2 \equiv \sum (D_1^2 + D_2^2 + \cdots + D_N^2)$$

is the least possible value when compared to all other possible lines fitted to that data. If the sum of squares for residuals is equal to zero, the calibration line is a perfect fit to the data. With a

mathematical treatment known as linear regression, one can find the “best” straight line through these real world points by minimizing the residuals.

This calibration model for the best-fit fit line requires that the line pass through the “centroid” of the points  $(\bar{X}, \bar{Y})$ . It can be shown that:

$$b = \frac{\sum_i (X_i - \bar{X})(Y_i - \bar{Y})}{\sum_i (X_i - \bar{X})^2} \tag{2.17}$$

$$a = \bar{Y} - b\bar{X} \tag{2.18}$$

The line thus calculated is known as the line of regression of  $Y$  on  $X$ , that is, the line indicating how  $Y$  varies when  $X$  is set to chosen values.

If  $X$  is the dependent variable, the definition is modified by considering horizontal instead of vertical deviations. In general these two definitions lead to different least square curves.

*Example 13* The following data were recorded for the potential  $E$  of an electrode, measured against the saturated calomel electrode, as a function of concentration  $C$  (moles liter<sup>-1</sup>).

| $-\log C$ | $E, \text{ mV}$ | $-\log C$ | $E, \text{ mV}$ |
|-----------|-----------------|-----------|-----------------|
| 1.00      | 106             | 2.10      | 174             |
| 1.10      | 115             | 2.20      | 182             |
| 1.20      | 121             | 2.40      | 187             |
| 1.50      | 139             | 2.70      | 211             |
| 1.70      | 153             | 2.90      | 220             |
| 1.90      | 158             | 3.00      | 226             |

Fit the best straight line to these data;  $X_i$  represents  $-\log C$ , and  $Y_i$  represents  $E$ . We will perform the calculation manually, using the following tabular lay-out.

| $X_i$             | $Y_i$             | $(X_i - \bar{X})$ | $(X_i - \bar{X})^2$ | $(Y_i - \bar{Y})$ | $(X_i - \bar{X})(Y_i - \bar{Y})$ |
|-------------------|-------------------|-------------------|---------------------|-------------------|----------------------------------|
| 1.00              | 106               | -0.975            | 0.951               | -60               | 58.5                             |
| 1.10              | 115               | -0.875            | 0.766               | -51               | 44.6                             |
| 1.20              | 121               | -0.775            | 0.600               | -45               | 34.9                             |
| 1.50              | 139               | -0.475            | 0.226               | -27               | 12.8                             |
| 1.70              | 153               | -0.275            | 0.076               | -13               | 3.6                              |
| 1.90              | 158               | -0.075            | 0.006               | -8                | 0.6                              |
| 2.10              | 174               | +0.125            | 0.016               | 8                 | 1.0                              |
| 2.20              | 182               | 0.225             | 0.051               | 16                | 3.6                              |
| 2.40              | 187               | 0.425             | 0.181               | 21                | 8.9                              |
| 2.70              | 211               | 0.725             | 0.526               | 45                | 32.6                             |
| 2.90              | 220               | 0.925             | 0.856               | 54                | 50.0                             |
| 3.00              | 226               | 1.025             | 1.051               | 60                | 61.5                             |
| $\Sigma X_i$ 23.7 | $\Sigma Y_i$ 1992 | $\Sigma 0$        | $\Sigma 5.306$      | $\Sigma 0$        | $\Sigma 312.6$                   |
| $\bar{X} = 1.975$ | $\bar{Y} = 166$   |                   |                     |                   |                                  |

Now substituting the proper terms into Equation 17, the slope is:

$$b = \frac{312.6}{5.306} = 58.91$$

and from Equation 18, and substituting the “centroid” values of the points  $(\bar{X}, \bar{Y})$ , the intercept is:

$$a = 166 - 58.91(1.975) = 49.64$$

The best-fit equation is therefore:

$$E = 49.64 - 58.91 \log C$$

**2.3.10.2 Errors in the Slope and Intercept of the Best-fit Line.** Upon examination of the plot of pairs of data points, the calibration line, it will be obvious that the precision involved in analyzing an unknown sample will be considerably poorer than that indicated by replicate error alone. The scatter of these original points about the calibration line is a good measure of the error to be expected in analyzing an unknown sample. And this same error is considerably larger than the replication error because it will include other sources of variability due to a variety of causes. One possible source of variability might be the presence of different amounts of an extraneous material in the various samples used to establish the calibration curve. While this variability causes scatter about the calibration curve, it will not be reflected in the replication error of any one sample if the sample is homogeneous.

The scatter of the points around the calibration line or random errors are of importance since the best-fit line will be used to estimate the concentration of test samples by interpolation. The method used to calculate the random errors in the values for the slope and intercept is now considered. We must first calculate the standard deviation  $s_{Y/X}$ , which is given by:

$$s_{Y/X} = \sqrt{\frac{\sum_i (Y_i - \hat{Y})^2}{N - 2}} \quad (2.19)$$

Equation 19 utilizes the *Y-residuals*,  $Y_i - \hat{Y}$ , where  $\hat{Y}_i$  are the points on the calculated best-fit line or the fitted  $Y_i$  values. The appropriate number of degrees of freedom is  $N - 2$ ; the minus 2 arises from the fact that linear calibration lines are derived from both a slope and an intercept which leads to a loss of two degrees of freedom.

Now we can calculate the standard deviations for the slope and the intercept. These are given by:

$$s_b = \frac{s_{Y/X}}{\sqrt{\sum_i (X_i - \bar{X})^2}} \quad (2.20)$$

$$s_a = s_{Y/X} \sqrt{\frac{\sum_i X_i^2}{N \sum_i (X_i - \bar{X})^2}} \quad (2.21)$$

The confidence limits for the slope are given by  $b \pm t_b$ , where the  $t$ -value is taken at the desired confidence level and  $(N - 2)$  degrees of freedom. Similarly, the confidence limits for the intercept are given by  $a \pm ts_a$ . The closeness of  $\hat{x}$  to  $x_i$  is answered in terms of a confidence interval for  $x_0$  that extends from an upper confidence (UCL) to a lower confidence (LCL) level. Let us choose 95% for the confidence interval. Then, remembering that this is a two-tailed test (UCL and LCL), we obtain from a table of Student's  $t$  distribution the critical value of  $t_c$  ( $t_{0.975}$ ) and the appropriate number of degrees of freedom.

*Example 14* For the best-fit line found in Example 13, express the result in terms of confidence intervals for the slope and intercept. We will choose 95% for the confidence interval.

The standard deviation  $s_{Y/X}$  is given by Equation 19, but first a supplementary table must be constructed for the  $Y$  residuals and other data which will be needed in subsequent equations.

| $\hat{Y}$      | $(Y_i - \hat{Y})$ | $(Y_i - \hat{Y})^2$ | $X_i^2$ |
|----------------|-------------------|---------------------|---------|
| 108.6          | 2.55              | 6.50                | 1.00    |
| 114.4          | -0.56             | 0.31                | 1.21    |
| 120.3          | -0.67             | 0.45                | 1.44    |
| 138.0          | -1.00             | 1.00                | 2.25    |
| 149.8          | -3.21             | 10.32               | 2.89    |
| 161.6          | 3.57              | 12.94               | 3.61    |
| 173.4          | -0.65             | 0.42                | 4.41    |
| 179.2          | -2.76             | 7.61                | 4.84    |
| 191.0          | 4.02              | 16.16               | 5.76    |
| 208.7          | -2.30             | 5.30                | 7.29    |
| 220.5          | 0.48              | 0.23                | 8.41    |
| 226.4          | 0.40              | 0.16                | 9.00    |
| $\Sigma$ 61.20 |                   | $\Sigma$ 52.11      |         |

Now substitute the appropriate values into Equation 19 where there are  $12 - 2 = 10$  degrees of freedom:

$$s_{X/Y} = \sqrt{\frac{61.20}{10}} = 2.47$$

We can now calculate  $s_b$  and  $s_a$  from Equations 20 and 21, respectively:

$$s_b = \frac{s_{Y/X}}{\sqrt{5.31}} = 1.07$$

and

$$s_a = 2.47 \sqrt{\frac{52.11}{12(5.306)}} = 2.23$$

Now, using a two-tailed value for Student's  $t$ :

$$b \pm ts_b = 58.91 \pm 2.23(1.07) = 58.91 \pm 2.39$$

$$a \pm ts_a = 49.64 \pm 2.23(2.23) = 49.64 \pm 4.97$$

The best-fit equation expressed in terms of the confidence intervals for the slope and intercept is:

$$E = (49.6_4 \pm 5.0) - (58.9_1 \pm 2.43) \log C$$

To conclude the discussion about the best-fit line, the following relationship can be shown to exist among  $Y$ ,  $\hat{Y}$ , and  $\bar{Y}$ :

$$\sum_{i=1}^N (Y_i - \bar{Y})^2 = \sum_{i=1}^N (\hat{Y}_i - \bar{Y})^2 + \sum_{i=1}^N (Y_i - \hat{Y}_i)^2 \quad (2.22)$$

The term on the left-hand side is a constant and depends only on the constituent values provided by the reference laboratory and does not depend in any way upon the calibration. The two terms on the right-hand side of the equation show how this constant value is apportioned between the two quantities that are themselves summations, and are referred to as the sum of squares due to regression and the sum of squares due to error. The latter will be the smallest possible value that it can possibly be for the given data.

### 2.3.11 Control Charts

It is often important in practice to know when a process has changed sufficiently so that steps may be taken to remedy the situation. Such problems arise in quality control where one must, often quickly, decide whether observed changes are due to simple chance fluctuations or to actual changes in the amount of a constituent in successive production lots, mistakes of employees, etc. Control charts provide a useful and simple method for dealing with such problems.

The chart consists of a central line and two pairs of limit lines or simply of a central line and one pair of control limits. By plotting a sequence of points in order, a continuous record of the quality characteristic is made available. Trends in data or sudden lack of precision can be made evident so that the causes may be sought.

The control chart is set up to answer the question of whether the data are in statistical control, that is, whether the data may be regarded as random samples from a single population of data. Because of this feature of testing for randomness, the control chart may be useful in searching out systematic sources of error in laboratory research data as well as in evaluating plant-production or control-analysis data.<sup>1</sup>

To set up a control chart, individual observations might be plotted in sequential order and then compared with control limits established from sufficient past experience. Limits of  $\pm 1.96\sigma$  corresponding to a confidence level of 95%, might be set for control limits. The probability of a future observation falling outside these limits, based on chance, is only 1 in 20. A greater proportion of scatter might indicate a nonrandom distribution (a systematic error). It is common practice with some users of control charts to set inner control limits, or warning limits, at  $\pm 1.96\sigma$  and outer control limits of  $\pm 3.00\sigma$ . The outer control limits correspond to a confidence level of 99.8%, or a probability of 0.002 that a point will fall outside the limits. One-half of this probability corresponds to a high result and one-half to a low result. However, other confidence limits can be used as well; the choice in each case depends on particular circumstances.

Special attention should be paid to one-sided deviation from the control limits, because systematic errors more often cause deviation in one direction than abnormally wide scatter. Two systematic errors of opposite sign would of course cause scatter, but it is unlikely that both would have entered at the same time. It is not necessary that the control chart be plotted in a time sequence. In any

<sup>1</sup> G. Wernimont, *Ind. Eng. Chem., Anal. Ed.* **18**:587 (1946); J. A. Mitchell, *ibid.* **19**:961 (1947).

situation where relatively large numbers of units or small groups are to be compared, the control chart is a simple means of indicating whether any unit or group is out of line. Thus laboratories, production machines, test methods, or analysts may be put arbitrarily into a horizontal sequence.

Usually it is better to plot the means of small groups of observations on a control chart, rather than individual observations. The random scatter of averages of pairs of observations is  $1/(2)^{1/2} = 0.71$  as great as that of single observations, and the likelihood of two “wild” observations in the same direction is vanishing small. The groups of two to five observations should be chosen in such a way that only change variations operate within the group, whereas assignable causes are sought for variations between groups. If duplicate analyses are performed each day, the pairs form logical groups.

Some measure of dispersion of the subgroup data should also be plotted as a parallel control chart. The most reliable measure of scatter is the standard deviation. For small groups, the range becomes increasingly significant as a measure of scatter, and it is usually a simple matter to plot the range as a vertical line and the mean as a point on this line for each group of observations.

### 3.1 NOMENCLATURE OF INORGANIC COMPOUNDS

---

The following synopsis of rules for naming inorganic compounds and the examples given in explanation are not intended to cover all the possible cases. For a more comprehensive and detailed description, see G. J. Leigh (ed.), *Nomenclature of Inorganic Chemistry*, 3d ed., Blackwell Scientific Publications, Oxford, 1990. This 289-page publication contains the Recommendations 1990 of the Commission on Nomenclature of Inorganic Chemistry and was prepared under the auspices of the International Union of Pure and Applied Chemistry (IUPAC). In particular, the latest report should be consulted for coordination compounds, boron compounds, and crystalline phases of variable composition.

#### 3.1.1 Writing Formulas

**3.1.1.1 Mass Number, Atomic Number, Number of Atoms, and Ionic Charge.** The mass number, atomic number, number of atoms, and ionic charge of an element are indicated by means of four indices placed around the symbol:

|               |               |                 |                     |
|---------------|---------------|-----------------|---------------------|
| mass number   | <b>SYMBOL</b> | ionic charge    | $^{15}\text{N}_2^-$ |
| atomic number |               | number of atoms |                     |

Ionic charge should be indicated by an Arabic superscript numeral preceding the plus or minus sign:  $\text{Mg}^{2+}$ ,  $\text{PO}_4^{3-}$ .

**3.1.1.2 Placement of Atoms in a Formula.** The electropositive constituent (cation) is placed first in a formula. If the compound contains more than one electropositive or more than one electronegative constituent, the sequence within each class should be in alphabetical order of their symbols.

The alphabetical order may be different in formulas and names; for example,  $\text{NaNH}_4\text{HPO}_4$ , ammonium sodium hydrogen phosphate.

Acids are treated as hydrogen salts. Hydrogen is cited last among the cations.

When there are several types of ligands, anionic ligands are cited before the neutral ligands.

**3.1.1.3 Binary Compounds between Nonmetals.** For binary compounds between nonmetals, that constituent should be placed first which appears earlier in the sequence:

Rn, Xe, Kr, Ar, Ne, He, B, Si, C, Sb, As, P, N, H, Te, Se, S, At, I, Br, Cl, O, F

*Examples:*  $\text{AsCl}_3$ ,  $\text{SbH}_3$ ,  $\text{H}_3\text{Te}$ ,  $\text{BrF}_3$ ,  $\text{OF}_2$ , and  $\text{N}_4\text{S}_4$ .

**3.1.1.4 Chain Compounds.** For chain compounds containing three or more elements, the sequence should be in accordance with the order in which the atoms are actually bound in the molecule or ion.

*Examples:*  $\text{SCN}^-$  (thiocyanate),  $\text{HSCN}$  (hydrogen thiocyanate or thiocyanic acid),  $\text{HNCO}$  (hydrogen isocyanate),  $\text{HONC}$  (hydrogen fulminate), and  $\text{HPH}_2\text{O}_2$  (hydrogen phosphinate).

**3.1.1.5 Use of Centered Period.** A centered period is used to denote water of hydration, other solvates, and addition compounds; for example,  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ , copper(II) sulfate 5-water (or pentahydrate).

**3.1.1.6 Free Radicals.** In the formula of a polyatomic radical an unpaired electron(s) is(are) indicated by a dot placed as a right superscript to the parentheses (or square bracket for coordination compounds). In radical ions the dot precedes the charge. In structural formulas, the dot may be placed to indicate the location of the unpaired electron(s).

*Examples:*  $(\text{HO})^\cdot$   $(\text{O}_2)^{2\cdot}$   $(\dot{\text{N}}\text{H}_3)$

**3.1.1.7 Enclosing Marks.** Where it is necessary in an inorganic formula, enclosing marks (parentheses, braces, and brackets) are nested within square brackets as follows:

$[()]$ ,  $[{} \{ () \}]$ ,  $[{} \{ [ () ] \}]$ ,  $[{} \{ [ {} \{ () \} ] \}]$

In an inorganic name the nesting order is different:  $\{ \{ \{ [ () ] \} \} \}$ , and so on.

**3.1.1.8 Molecular Formula.** For compounds consisting of discrete molecules, a formula in accordance with the correct molecular weight of the compound should be used.

*Examples:*  $\text{S}_2\text{Cl}_2$ ,  $\text{S}_8$ ,  $\text{N}_2\text{O}_4$ , and  $\text{H}_4\text{P}_2\text{O}_6$ ; not  $\text{SCl}$ ,  $\text{S}$ ,  $\text{NO}_2$ , and  $\text{H}_2\text{PO}_3$ .

**3.1.1.9 Structural Formula and Prefixes.** In the structural formula the sequence and spatial arrangement of the atoms in a molecule are indicated.

*Examples:*  $\text{NaO}(\text{O}=\text{C})\text{H}$  (sodium formate),  $\text{Cl}-\text{S}-\text{S}-\text{Cl}$  (disulfur dichloride).

Structural prefixes should be italicized and connected with the chemical formula by a hyphen: *cis-*, *trans-*, *anti-*, *syn-*, *cyclo-*, *catena-*, *o-* or *ortho-*, *m-* or *meta-*, *p-* or *para-*, *sec-* (secondary), *tert-* (tertiary), *v-* (vicinal), *meso-*, *as-* for asymmetrical, and *s-* for symmetrical.

The sign of optical rotation is placed in parentheses, (+) for dextrorotary, (−) for levorotary, and (±) for racemic, and placed before the formula. The wavelength (in nanometers) is indicated by a right subscript; unless indicated otherwise, it refers to the sodium D-line.

The italicized symbols *d*- (for deuterium) and *t*- (for tritium) are placed after the formula and connected to it by a hyphen. The number of deuterium or tritium atoms is indicated by a subscript to the symbol.

*Examples:*

|                                                                  |                                                          |
|------------------------------------------------------------------|----------------------------------------------------------|
| <i>cis</i> -[PtCl <sub>2</sub> (NH <sub>3</sub> ) <sub>2</sub> ] | methan- <i>d</i> <sub>3</sub> -ol                        |
| di- <i>tert</i> -butyl sulfate                                   | (+) <sub>589</sub> [Co(en) <sub>3</sub> ]Cl <sub>2</sub> |
| methan-ol- <i>d</i>                                              |                                                          |

### 3.1.2 Naming Compounds

**3.1.2.1 Names and Symbols for Elements.** Names and symbols for the elements are given in Table 3.2. Wolfram is preferred to tungsten but the latter is used in the United States. In forming a complete name of a compound, the name of the electropositive constituent is left unmodified except when it is necessary to indicate the valency (see oxidation number and charge number, formerly the Stock and Ewens-Bassett systems). The order of citation follows the alphabetical listing of the names of the cations followed by the alphabetical listing of the anions and ligands. The alphabetical citation is maintained regardless of the number of each ligand.

*Example:* K[AuS(S<sub>2</sub>)] is potassium (disulfido)thioaurate(1-).

**3.1.2.2 Electronegative Constituents.** The name of a monatomic electronegative constituent is obtained from the element name with its ending (-en, -ese, -ic, -ine, -ium, -ogen, -on, -orus, -um, -ur, -y, or -ygen) replaced by -ide. The elements bismuth, cobalt, nickel, zinc, and the noble gases are used unchanged with the ending -ide. Homopolyatomic ligands will carry the appropriate prefix. A few Latin names are used with affixes: cupr- (copper), aur- (gold), ferr- (iron), plumb- (lead), argent- (silver), and stann- (tin).

For binary compounds the name of the element standing later in the sequence in Sec. 3.1.1.3 is modified to end in -ide. Elements other than those in the sequence of Sec. 3.1.1.3 are taken in the reverse order of the following sequence, and the name of the element occurring last is modified to end in -ide; e.g., calcium stannide.

#### ELEMENT SEQUENCE

**3.1.2.3 Stoichiometric Proportions.** The stoichiometric proportions of the constituents in a formula may be denoted by Greek numerical prefixes: mono-, di-, tri-, tetra-, penta-, hexa-, hepta-, octa-, nona- (Latin), deca-, undeca- (Latin), dodeca-, . . . , icos- (20), henicos- (21), . . . , triconta- (30), tetraconta- (40), . . . , hecta- (100), and so on, preceding without a hyphen the names of the elements to which they refer. The prefix mono can usually be omitted; occasionally hemi- (½) and sesqui- (¾) are used. No elisions are made when using numerical prefixes except in the case of icos- when the letter “i” is elided in docosa- and tricos-. Beyond 10, prefixes may be replaced by Arabic numerals.

When it is required to indicate the number of entire groups of atoms, the multiplicative numerals bis-, tris-, tetrakis-, pentakis-, and so on, are used (i.e., -kis is added starting from tetra-). The entity to which they refer is placed in parentheses.

*Examples:*  $\text{Ca}[\text{PF}_6]_2$ , calcium bis(hexafluorophosphate); and  $(\text{C}_{10}\text{H}_{21})_3\text{PO}_4$ , tris(decyl) phosphate instead of tridecyl which is  $(\text{C}_{13}\text{H}_{27}-)$ .

Composite numeral prefixes are built up by citing units first, then tens, then hundreds, and so on. For example, 43 is written tritetraconta- (or tritetracontakis-).

In indexing it may be convenient to italicize a numerical prefix at the beginning of the name and connect it to the rest of the name with a hyphen; e.g., *di*-nitrogen pentaoxide (indexed under the letter “n”).

**3.1.2.4 Oxidation and Charge Numbers.** The *oxidation number* (Stock system) of an element is indicated by a Roman numeral placed in parentheses immediately following the name of the element. For zero, the cipher 0 is used. When used in conjunction with symbols the Roman numeral may be placed above and to the right. The *charge number* of an ion (Ewens-Bassett system) rather than the oxidation state is indicated by an Arabic numeral followed by the sign of the charge cited and is placed in parentheses immediately following the name of the ion.

*Examples:*  $\text{P}_2\text{O}_5$ , diphosphorus pentaoxide or phosphorus(V) oxide;  $\text{Hg}_2^{2+}$ , mercury(I) ion or dimercury(2+) ion;  $\text{K}_2[\text{Fe}(\text{CN})_6]$ , potassium hexacyanoferrate(II) or potassium hexacyanoferrate(4-);  $\text{Pb}_2^{\text{II}}\text{Pb}^{\text{IV}}\text{O}_4$ , dilead(II) lead(IV) oxide or trilead tetraoxide.

Where it is not feasible to define an oxidation state for each individual member of a group, the overall oxidation level of the group is defined by a formal ionic charge to avoid the use of fractional oxidation states; for example,  $\text{O}_2^-$ .

**3.1.2.5 Collective Names.** Collective names include:

Halogens (F, Cl, Br, I, At)

Chalcogens (O, S, Se, Te, Po)

Alkali metals (Li, Na, K, Rb, Cs, Fr)

Alkaline-earth metals (Ca, Sr, Ba, Ra)

Lanthanoids or lanthanides (La to Lu)

Rare-earth metals (Sc, Y, and La to Lu inclusive)

Actinoids or actinides (Ac to Lr, those whose 5f shell is being filled)

Noble gases (He to Rn)

A transition element is an element whose atom has an incomplete *d* subshell, or which gives rise to a cation or cations with an incomplete *d* subshell.

**3.1.2.6 Isotopically Labeled Compounds.** The hydrogen isotopes are given special names:  $^1\text{H}$  (protium),  $^2\text{H}$  or D (deuterium), and  $^3\text{H}$  or T (tritium). The superscript designation is preferred because D and T disturb the alphabetical ordering in formulas.

Other isotopes are designated by mass numbers:  $^{10}\text{B}$  (boron-10).

Isotopically labeled compounds may be described by inserting the italic symbol of the isotope in brackets into the name of the compound; for example,  $\text{H}^{36}\text{Cl}$  is hydrogen chloride[ $^{36}\text{Cl}$ ] or hydrogen chloride-36, and  $^2\text{H}^{38}\text{Cl}$  is hydrogen [ $^2\text{H}$ ] chloride[ $^{38}\text{Cl}$ ] or hydrogen-2 chloride-38.

**3.1.2.7 Allotropes.** Systematic names for gaseous and liquid modifications of elements are sometimes needed. Allotropic modifications of an element bear the name of the atom together with the descriptor to specify the modification. The following are a few common examples:

| Symbol         | Trivial name                      | Systematic name |
|----------------|-----------------------------------|-----------------|
| H              | Atomic hydrogen                   | Monohydrogen    |
| O <sub>2</sub> | (Common oxygen)                   | Dioxygen        |
| O <sub>3</sub> | Ozone                             | Trixygen        |
| P <sub>4</sub> | White phosphorus                  | Tetraphosphorus |
| S <sub>8</sub> | $\alpha$ -Sulfur, $\beta$ -Sulfur | Octasulfur      |
| S <sub>n</sub> | $\mu$ -Sulfur (plastic sulfur)    | Polysulfur      |

Trivial (customary) names are used for the amorphous modification of an element.

**3.1.2.8 Heteroatomic and Other Anions.** A few heteroatomic anions have names ending in -ide. These are

|                                                         |                                         |
|---------------------------------------------------------|-----------------------------------------|
| —OH, hydroxide ion (not hydroxyl)                       | —NH—, imide ion                         |
| —CN, cyanide ion                                        | —NH—NH <sub>2</sub> , hydrazide ion     |
| —HF <sub>2</sub> <sup>−</sup> , hydrogen difluoride ion | —NHOH, hydroxylamide ion                |
| —NH <sub>2</sub> , amide ion                            | —HS <sup>−</sup> , hydrogen sulfide ion |

Added to these anions are

|                                              |                      |
|----------------------------------------------|----------------------|
| —I <sub>3</sub> <sup>−</sup> , triiodide ion | —O—O—, peroxide ion  |
| —N <sub>3</sub> , azide ion                  | —S—S—, disulfide ion |
| —O <sub>3</sub> , ozonide ion                |                      |

**3.1.2.9 Binary Compounds of Hydrogen.** Binary compounds of hydrogen with the more electropositive elements are designated hydrides (NaH, sodium hydride).

Volatile hydrides, except those of Periodic Group VII and of oxygen and nitrogen, are named by citing the root name of the element (penultimate consonant and Latin affixes, Sec. 3.1.2.2) followed by the suffix -ane. Exceptions are water, ammonia, hydrazine, phosphine, arsine, stibine, and bismuthine.

*Examples:* B<sub>2</sub>H<sub>6</sub>, diborane; B<sub>10</sub>H<sub>14</sub>, decaborane(14); B<sub>10</sub>H<sub>16</sub>, decaborane(16); P<sub>2</sub>H<sub>4</sub>, diphosphane; Sn<sub>2</sub>H<sub>6</sub>, distannane; H<sub>2</sub>Se<sub>2</sub>, diselane; H<sub>2</sub>Te<sub>2</sub>, ditellane; H<sub>2</sub>S<sub>5</sub>, pentasulfane; and PbH<sub>4</sub>, plum-bane.

**3.1.2.10 Neutral Radicals.** Certain neutral radicals have special names ending in -yl:

|                  |            |                  |                  |
|------------------|------------|------------------|------------------|
| HO               | hydroxyl   | ClO <sub>3</sub> | perchloryl*      |
| CO               | carbonyl   | CrO <sub>2</sub> | chromyl          |
| ClO              | chlorosyl* | NO               | nitrosyl         |
| ClO <sub>2</sub> | chloryl*   | NO <sub>2</sub>  | nitryl (nitroyl) |

\* Similarly for the other halogens.

|                               |                     |                  |           |
|-------------------------------|---------------------|------------------|-----------|
| PO                            | phosphoryl          | SeO              | seleninyl |
| SO                            | sulfinyl (thionyl)  | SeO <sub>2</sub> | selenonyl |
| SO <sub>2</sub>               | sulfonyl (sulfuryl) | UO <sub>2</sub>  | uranyl    |
| S <sub>2</sub> O <sub>5</sub> | disulfuryl          | NpO <sub>2</sub> | neptunyl† |

Radicals analogous to the above containing other chalcogens in place of oxygen are named by adding the prefixes thio-, seleno-, and so on; for example, PS, thiophosphoryl; CS, thiocarbonyl.

### 3.1.3 Cations

**3.1.3.1 Monatomic Cations.** Monatomic cations are named as the corresponding element; for example, Fe<sup>2+</sup>, iron(II) ion; Fe<sup>3+</sup>, iron(III) ion.

This principle also applies to polyatomic cations corresponding to radicals with special names ending in -yl (Sec. 3.1.2.10); for example, PO<sup>+</sup>, phosphoryl cation; NO<sup>+</sup>, nitrosyl cation; NO<sub>2</sub><sup>+</sup>, nitryl cation; O<sub>2</sub><sup>+</sup>, oxygenyl cation.

Use of the oxidation number and charge number extends the range for radicals; for example, UO<sub>2</sub><sup>+</sup> uranyl(VI) or uranyl(2+) cation; UO<sub>2</sub><sup>+</sup>, uranyl(V) or uranyl(1+) cation.

**3.1.3.2 Polyatomic Cations.** Polyatomic cations derived by addition of more protons than required to give a neutral unit to polyatomic anions are named by adding the ending -onium to the root of the name of the anion element; for example, PH<sub>4</sub><sup>+</sup>, phosphonium ion; H<sub>2</sub>I<sup>+</sup>, iodonium ion; H<sub>3</sub>O<sup>+</sup>, oxonium ion; CH<sub>3</sub>OH<sub>2</sub><sup>+</sup>, methyl oxonium ion.

*Exception:* The name ammonium is retained for the NH<sub>4</sub><sup>+</sup> ion; similarly for substituted ammonium ions; for example, NF<sub>4</sub><sup>+</sup>, tetrafluoroammonium ion.

Substituted ammonium ions derived from nitrogen bases with names ending in -amine receive names formed by changing -amine into -ammonium. When known by a name not ending in -amine, the cation name is formed by adding the ending -ium to the name of the base (eliding the final vowel); e.g., anilinium, hydrazinium, imidazolium, acetonium, dioxanium.

Exceptions are the names uronium and thiouronium derived from urea and thiourea, respectively.

**3.1.3.3 Multiple Ions from One Base.** Where more than one ion is derived from one base, the ionic charges are indicated in their names: N<sub>2</sub>H<sub>5</sub><sup>+</sup>, hydrazinium(1+) ion; N<sub>2</sub>H<sub>6</sub><sup>2+</sup>, hydrazinium(2+) ion.

### 3.1.4 Anions

See Secs. 3.1.2.2 and 3.1.2.8 for naming monatomic and certain polyatomic anions. When an organic group occurs in an inorganic compound, organic nomenclature (*q.v.*) is followed to name the organic part.

**3.1.4.1 Protonated Anions.** Ions such as HSO<sub>4</sub><sup>-</sup> are recommended to be named hydrogensulfate with the two words written as one following the usual practice for polyatomic anions. However, in the *Nomenclature of Organic Chemistry*, 1979 edition, hydrogen is used as a separate word; this practice is followed in this Handbook.

† Similarly for the other actinoid elements.

**3.1.4.2 Other Polyatomic Anions.** Names for other polyatomic anions consist of the root name of the central atom with the ending -ate and followed by the valence of the central atom expressed by its oxidation number. Atoms and groups attached to the central atom are treated as ligands in a complex.

*Examples:*  $[\text{Sb}(\text{OH})_6]^-$ , hexahydroxoantimonate(V);  $[\text{Fe}(\text{CN})_6]^{3-}$ , hexacyanoferrate(III);  $[\text{Co}(\text{NO}_2)_6]^{3-}$ , hexanitritocobaltate(III);  $[\text{TiO}(\text{C}_2\text{O}_4)_2(\text{H}_2\text{O})_2]^{2-}$ , oxobisoxalatodiaquatitanate(IV);  $[\text{PCl}_6]^-$ , hexachlorophosphate(V).

Exceptions to the use of the root name of the central atom are antimonate, bismuthate, carbonate, cobaltate, nickelate (or niccolate), nitrate, phosphate, tungstate (or wolframate), and zincate.

**3.1.4.3 Anions of Oxygen.** Oxygen is treated in the same manner as other ligands with the number of -oxo groups indicated by a suffix; for example,  $\text{SO}_3^{2-}$ , trioxosulfate.

The ending -ite, formerly used to denote a lower state of oxidation, may be retained in trivial names in these cases (note Sec. 3.1.5.3 also):

|                             |              |                             |               |
|-----------------------------|--------------|-----------------------------|---------------|
| $\text{AsO}_3^{3-}$         | arsenite     | $\text{NOO}_2^-$            | peroxonitrite |
| $\text{BrO}^-$              | hypobromite  | $\text{PO}_3^{3-}$          | phosphite*    |
| $\text{ClO}^-$              | hypochlorite | $\text{SO}_3^{2-}$          | sulfite       |
| $\text{ClO}_2^-$            | chlorite     | $\text{S}_2\text{O}_5^{2-}$ | disulfite     |
| $\text{IO}^-$               | hypoiodite   | $\text{S}_2\text{O}_4^{2-}$ | dithionite    |
| $\text{NO}_2^-$             | nitrite      | $\text{S}_2\text{O}_3^{2-}$ | thiosulfite   |
| $\text{N}_2\text{O}_2^{2-}$ | hyponitrite  | $\text{SeO}_3^{2-}$         | selenite      |

However, compounds known to be double oxides in the solid state are named as such; for example,  $\text{Cr}_2\text{CuO}_4$  (actually  $\text{Cr}_2\text{O}_3 \cdot \text{CuO}$ ) is chromium(III) copper(II) oxide (and not copper chromite).

**3.1.4.4 Isopolyanions.** Isopolyanions are named by indicating with numerical prefixes the number of atoms of the characteristic element. It is not necessary to give the number of oxygen atoms when the charge of the anion or the number of cations is indicated.

*Examples:*  $\text{Ca}_3\text{Mo}_7\text{O}_{24}$ , tricalcium 24-oxoheptamolybdate, may be shortened to tricalcium heptamolybdate; the anion,  $\text{Mo}_7\text{O}_{24}^{6-}$ , is heptamolybdate(6-);  $\text{S}_2\text{O}_7^{2-}$ , disulfate(2-);  $\text{P}_2\text{O}_7^{4-}$ , diphosphate(V)(4-).

When the characteristic element is partially or wholly present in a lower oxidation state than corresponds to its Periodic Group number, oxidation numbers are used; for example,  $[\text{O}_2\text{HP}-\text{O}-\text{PO}_3\text{H}]^{2-}$ , dihydrogendiphosphate(III,V)(2-).

A bridging group should be indicated by adding the Greek letter  $\mu$  immediately before its names and separating this from the rest of the complex by a hyphen. The atom or atoms of the characteristic element to which the bridging atom is bonded, is indicated by numbers.

*Examples:*  $[\text{O}_3\text{P}-\text{S}-\text{PO}_2-\text{O}-\text{PO}_3]^{5-}$ , 1,2- $\mu$ -thiotriphosphate(5-)  
 $[\text{S}_3\text{P}-\text{O}-\text{PS}_2-\text{O}-\text{PS}_3]^{5-}$ , di- $\mu$ -oxo-octathiotriphosphate(5-)

\* Named for esters formed from the hypothetical acid  $\text{P}(\text{OH})_3$ .

### 3.1.5 Acids

**3.1.5.1 Acids and -ide Anions.** Acids giving rise to the -ide anions (Sec. 3.1.2.2) should be named as hydrogen . . . -ide; for example, HCl, hydrogen chloride;  $\text{HN}_3$ , hydrogen azide.

Names such as hydrobromic acid refer to an aqueous solution, and percentages such as 48% HBr denote the weight/volume of hydrogen bromide in the solution.

**3.1.5.2 Acids and -ate Anions.** Acids giving rise to anions bearing names ending in -ate are treated as in Sec. 3.1.5.1; for example,  $\text{H}_2\text{GeO}_4$ , hydrogen germanate;  $\text{H}_4[\text{Fe}(\text{CN})_6]$ , hydrogen hexacyanoferrate(II).

**3.1.5.3 Trivial Names.** Acids given in Table 3.1 retain their trivial names due to long-established usage. Anions may be formed from these trivial names by changing -ous acid to -ite, and -ic acid to -ate. The prefix hypo- is used to denote a lower oxidation state and the prefix per- designates a higher oxidation state. The prefixes ortho- and meta- distinguish acids of differing water content; for example,  $\text{H}_4\text{SiO}_4$  is orthosilicic acid and  $\text{H}_2\text{SiO}_3$  is metasilicic acid. The anions would be named silicate(4-) and silicate(2-), respectively.

**3.1.5.4 Peroxo- Group.** When used in conjunction with the trivial names of acids, the prefix peroxo- indicates substitution of  $\text{—O—}$  by  $\text{—O—O—}$ .

**3.1.5.5 Replacement of Oxygen by Other Chalcogens.** Acids derived from oxoacids by replacement of oxygen by sulfur are called thioacids, and the number of replacements are given by prefixes di-, tri-, and so on. The affixes seleno- and telluro- are used analogously.

*Examples:*  $\text{HOO—C=S}$ , thiocarbonic acid;  $\text{HSS—C=S}$ , trithiocarbonic acid.

**3.1.5.6 Ligands Other than Oxygen and Sulfur.** See Sec. 3.1.7, Coordination Compounds, for acids containing ligands other than oxygen and sulfur (selenium and tellurium).

**3.1.5.7 Differences between Organic and Inorganic Nomenclature.** Organic nomenclature is largely built upon the scheme of substitution, that is, the replacement of hydrogen atoms by other atoms or groups. Although rare in inorganic nomenclature:  $\text{NH}_2\text{Cl}$  is called chloramine and  $\text{NHCl}_2$  dichloroamine. Other substitutive names are fluorosulfonic acid and chlorosulfonic acid derived from  $\text{HSO}_3\text{H}$ . These and the names aminosulfonic acid (sulfamic acid), iminodisulfonic acid, and nitritrisulfonic acid should be replaced by the following based on the concept that these names are formed by adding hydroxyl, amide, imide, and so on, groups together with oxygen atoms to a sulfur atom:

|                                  |                     |                                    |                            |
|----------------------------------|---------------------|------------------------------------|----------------------------|
| $\text{HSO}_3\text{F}$           | fluorosulfuric acid | $\text{NH}(\text{SO}_3\text{H})_2$ | imidobis(sulfuric) acid    |
| $\text{HSO}_3\text{Cl}$          | chlorosulfuric acid | $\text{N}(\text{SO}_3\text{H})_3$  | nitridotris(sulfuric) acid |
| $\text{NH}_2\text{SO}_3\text{H}$ | amidosulfuric acid  |                                    |                            |

### 3.1.6 Salts and Functional Derivatives of Acids

**3.1.6.1 Acid Halogenides.** For acid halogenides the name is formed from the corresponding acid radical if this has a special name (Sec. 3.1.2.10); for example,  $\text{NOCl}$ , nitrosyl chloride. In other cases these compounds are named as halogenide oxides with the ligands listed alphabetically; for example,  $\text{BiClO}$ , bismuth chloride oxide;  $\text{VCl}_2\text{O}$ , vanadium(IV) dichloride oxide.

**3.1.6.2 Anhydrides.** Anhydrides of inorganic acids are named as oxides; for example,  $\text{N}_2\text{O}_5$ , dinitrogen pentoxide.

**TABLE 3.1** Trivial Names Retained for Acids*Alphabetically by characteristic element.*

|                                               |                                           |                                                             |                                                 |
|-----------------------------------------------|-------------------------------------------|-------------------------------------------------------------|-------------------------------------------------|
| H <sub>3</sub> AsO <sub>4</sub>               | arsenic acid                              | H <sub>4</sub> P <sub>2</sub> O <sub>7</sub>                | diphosphoric acid (or pyro-phosphoric acid)     |
| H <sub>3</sub> AsO <sub>3</sub>               | arsenious acid                            | H <sub>4</sub> P <sub>2</sub> O <sub>8</sub>                | peroxodiphosphoric acid                         |
| H <sub>3</sub> BO <sub>3</sub>                | orthoboric acid (or boric acid)           | (HO) <sub>2</sub> OP                                        | diphosphoric(IV) acid or hypophosphoric acid    |
| HBO <sub>2</sub>                              | metaboric acid                            | (HO) <sub>2</sub> OP                                        |                                                 |
| HBrO <sub>3</sub>                             | bromic acid                               | (HO) <sub>2</sub> P—O                                       | diphosphoric(III,V) acid                        |
| HBrO <sub>2</sub>                             | bromous acid                              | (HO) <sub>2</sub> P—O                                       |                                                 |
| HBrO                                          | hypobromous acid                          | H <sub>2</sub> PHO <sub>3</sub>                             | phosphonic acid                                 |
| H <sub>2</sub> CO <sub>3</sub>                | carbonic acid                             | H <sub>2</sub> P <sub>2</sub> H <sub>2</sub> O <sub>5</sub> | diphosphonic acid                               |
| HOCN                                          | cyanic acid                               | HPH <sub>2</sub> O <sub>2</sub>                             | phosphinic acid (formerly hypophosphorous acid) |
| HNCO                                          | isocyanic acid                            | HReO <sub>4</sub>                                           | perrhenic acid                                  |
| HONC                                          | fulminic acid                             | H <sub>2</sub> ReO <sub>4</sub>                             | rhenic acid                                     |
| HClO <sub>4</sub>                             | perchloric acid                           | H <sub>2</sub> SO <sub>4</sub>                              | sulfuric acid                                   |
| HClO <sub>3</sub>                             | chloric acid                              | H <sub>2</sub> S <sub>2</sub> O <sub>7</sub>                | disulfuric acid                                 |
| HClO <sub>2</sub>                             | chlorous acid                             | H <sub>2</sub> SO <sub>5</sub>                              | peroxomonosulfuric acid                         |
| HClO                                          | hypochlorous acid                         | H <sub>2</sub> S <sub>2</sub> O <sub>3</sub>                | thiosulfuric acid                               |
| H <sub>2</sub> CrO <sub>4</sub>               | chromic acid                              | H <sub>2</sub> S <sub>2</sub> S <sub>6</sub>                | dithionic acid                                  |
| H <sub>2</sub> Cr <sub>2</sub> O <sub>7</sub> | dichromic acid                            | H <sub>2</sub> SO <sub>3</sub>                              | sulfurous acid                                  |
| H <sub>5</sub> IO <sub>6</sub>                | orthoperiodic acid                        | H <sub>2</sub> S <sub>2</sub> O <sub>5</sub>                | disulfurous acid                                |
| HIO <sub>4</sub>                              | periodic acid                             | H <sub>2</sub> S <sub>2</sub> O <sub>2</sub>                | thiosulfurous acid                              |
| HIO <sub>3</sub>                              | iodic acid                                | H <sub>2</sub> S <sub>2</sub> O <sub>4</sub>                | dithionous acid                                 |
| HIO                                           | hypoiodous acid                           | H <sub>2</sub> S <sub>x</sub> O <sub>6</sub>                | polythionic acid                                |
| HMnO <sub>4</sub>                             | permanganic acid                          | (x = 3, 4, . . . )                                          | (tri-, tetra-, . . . )                          |
| H <sub>2</sub> MnO <sub>4</sub>               | manganic acid                             | H <sub>2</sub> SO <sub>2</sub>                              | sulfoxylic acid                                 |
| HNO <sub>4</sub>                              | peroxonitric acid                         | HSb(OH) <sub>6</sub>                                        | hexahydroxoantimonic acid                       |
| HNO <sub>3</sub>                              | nitric acid                               | H <sub>2</sub> SeO <sub>4</sub>                             | selenic acid                                    |
| HNO <sub>2</sub>                              | nitrous acid                              | H <sub>2</sub> SeO <sub>3</sub>                             | selenious acid                                  |
| H <sub>2</sub> NO <sub>2</sub>                | nitroxylic acid                           | H <sub>4</sub> SiO <sub>4</sub>                             | orthosilicic acid                               |
| H <sub>2</sub> N <sub>2</sub> O <sub>2</sub>  | hyponitrous acid                          | H <sub>2</sub> SiO <sub>3</sub>                             | metasilicic acid                                |
| HOONO                                         | peroxonitrous acid                        | HTcO <sub>4</sub>                                           | pertechnetic acid                               |
| H <sub>3</sub> PO <sub>4</sub>                | orthophosphoric acid (or phosphoric acid) | H <sub>2</sub> TeO <sub>4</sub>                             | technetic acid                                  |
| HPO <sub>3</sub>                              | metaphosphoric acid                       | H <sub>6</sub> TeO <sub>6</sub>                             | orthotelluric acid                              |
| H <sub>3</sub> PO <sub>5</sub>                | peroxomonophosphoric acid                 |                                                             |                                                 |

**3.1.6.3 Esters.** Esters of inorganic acids are named as the salts; for example, (CH<sub>3</sub>)<sub>2</sub>SO<sub>4</sub>, dimethyl sulfate. However, if it is desired to specify the constitution of the compound, the nomenclature for coordination compounds should be used.

**3.1.6.4 Amides.** Names for amides are derived from the names of the acid radicals (or from the names of acids by replacing acid by amide); for example, SO<sub>2</sub>(NH<sub>2</sub>)<sub>2</sub>, sulfonyl diamide (or sulfuric diamide); NH<sub>2</sub>SO<sub>3</sub>H, sulfamidic acid (or amidosulfuric acid).

**3.1.6.5 Salts.** Salts containing acid hydrogen are named by adding the word hydrogen before the name of the anion (however, see Sec. 3.1.4.1), for example, KH<sub>2</sub>PO<sub>4</sub>, potassium dihydrogen phosphate; NaHCO<sub>3</sub>, sodium hydrogen carbonate (not bicarbonate); NaHPO<sub>3</sub>, sodium hydrogen phosphonate (only one acid hydrogen remaining).

Salts containing O<sup>2-</sup> and HO<sup>-</sup> anions are named oxide and hydroxide, respectively. Anions are cited in alphabetical order which may be different in formulas and names.

*Examples:* FeO(OH), iron(III) hydroxide oxide; VO(SO<sub>4</sub>), vanadium(IV) oxide sulfate.

**3.1.6.6 Multiplicative Prefixes.** The multiplicative prefixes bis, tris, etc., are used with certain anions for indicating stoichiometric proportions when di, tri, etc., have been preempted to designate condensed anions; for example,  $\text{AlK}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$ , aluminum potassium bis(sulfate) 12-water (recall that disulfate refers to the anion  $\text{S}_2\text{O}_7^{2-}$ ).

**3.1.6.7 Crystal Structure.** The structure type of crystals may be added in parentheses and in italics after the name; the latter should be in accordance with the structure. When the typename is also the mineral name of the substance itself, italics are not used.

*Examples:*  $\text{MgTiO}_3$ , magnesium titanium trioxide (*ilmenite* type);  $\text{FeTiO}_3$ , iron(II) titanium trioxide (*ilmenite*).

### 3.1.7 Coordination Compounds

**3.1.7.1 Naming a Coordination Compound.** To name a coordination compound, the names of the ligands are attached directly in front of the name of the central atom. The ligands are listed in alphabetical order regardless of the number of each and with the name of a ligand treated as a unit. Thus “diammine” is listed under “a” and “dimethylamine” under “d.” The oxidation number of the central atom is stated last by either the oxidation number or charge number.

**3.1.7.2 Anionic Ligands.** Whether inorganic or organic, the names for anionic ligands end in -o (eliding the final -e, if present, in the anion name). Enclosing marks are required for inorganic anionic ligands containing numerical prefixes, and for thio, seleno, and telluro analogs of oxo anions containing more than one atom.

If the coordination entity is negatively charged, the cations paired with the complex anion (with -ate ending) are listed first. If the entity is positively charged, the anions paired with the complex cation are listed immediately afterward.

The following anions do not follow the nomenclature rules:

|                   |                    |                         |                               |
|-------------------|--------------------|-------------------------|-------------------------------|
| $\text{F}^-$      | fluoro             | $\text{HO}_2^-$         | hydrogen peroxo               |
| $\text{Cl}^-$     | chloro             | $\text{S}^{2-}$         | thio (only for single sulfur) |
| $\text{Br}^-$     | bromo              | $\text{S}_2^{2-}$       | disulfido                     |
| $\text{I}^-$      | iodo               | $\text{HS}^-$           | mercapto                      |
| $\text{O}^{2-}$   | oxo                | $\text{CN}^-$           | ciano                         |
| $\text{H}^-$      | hydrido (or hydro) | $\text{CH}_2\text{O}^-$ | methoxo or methanolato        |
| $\text{OH}^-$     | hydroxo            | $\text{CH}_2\text{S}^-$ | methylthio or methanethiolato |
| $\text{O}_2^{2-}$ | peroxo             |                         |                               |

**3.1.7.3 Neutral and Cationic Ligands.** Neutral and cationic ligands are used without change in name and are set off with enclosing marks. Water and ammonia, as neutral ligands, are called “aqua” and “ammine,” respectively. The groups NO and CO, when linked directly to a metal atom, are called nitrosyl and carbonyl, respectively.

**3.1.7.4 Attachment Points of Ligands.** The different points of attachment of a ligand are denoted by adding italicized symbol(s) for the atom or atoms through which the attachment occurs at the end of the name of the ligand; e.g., glycine-*N* or glycinate-*O,N*. If the same element is involved in different possible coordination sites, the position in the chain or ring to which the element is attached is indicated by numerical superscripts: e.g., tartrato(3-)- $\text{O}^1, \text{O}^2$ , or tartrato(4-)- $\text{O}^2, \text{O}^3$  or tartrato(2-)- $\text{O}^1, \text{O}^4$ .

**3.1.7.5 Abbreviations for Ligand Names.** Except for certain hydrocarbon radicals, for ligand (L) and metal (M), and a few with H, all abbreviations are in lowercase letters and do not involve hyphens. In formulas, the ligand abbreviation is set off with parentheses. Some common abbreviations are

|                     |                                                      |                    |                                           |
|---------------------|------------------------------------------------------|--------------------|-------------------------------------------|
| Ac                  | acetyl                                               | en                 | ethylenediamine                           |
| acac                | acetylacetonato                                      | Him                | imidazole                                 |
| Hacac               | acetylacetone                                        | H <sub>2</sub> ida | iminodiacetic acid                        |
| Hba                 | benzoylacetone                                       | Me                 | methyl                                    |
| Bzl                 | benzyl                                               | H <sub>3</sub> nta | nitrilotriacetic acid                     |
| Hbg                 | biguanide                                            | nbd                | norbornadiene                             |
| bpy                 | 2,2'-bipyridine                                      | ox                 | oxalato(2-) from parent H <sub>2</sub> ox |
| Bu                  | butyl                                                | phen               | 1,10-phenanthroline                       |
| Cy                  | cyclohexyl                                           | Ph                 | phenyl                                    |
| D <sub>2</sub> dea  | diethanolamine                                       | pip                | piperidine                                |
| dien                | diethylenetriamine                                   | Pr                 | propyl                                    |
| dmf                 | dimethylformamide                                    | pn                 | propylenediamine                          |
| H <sub>2</sub> dmg  | dimethylglyoxime                                     | Hpz                | pyrazole                                  |
| dmg                 | dimethylglyoximato(2-)                               | py                 | pyridine                                  |
| Hdmg                | dimethylglyoximato(1-)                               | thf                | tetrahydrofuran                           |
| dmsO                | dimethylsulfoxide                                    | tu                 | thiourea                                  |
| Et                  | ethyl                                                | H <sub>3</sub> tea | triethanolamine                           |
| H <sub>4</sub> edta | ethylenediaminetetraacetic acid                      | tren               | 2,2',2''-triiminotriethylamine            |
| Hedta, edta         | coordinated ions derived<br>from H <sub>4</sub> edta | trien              | triethylenetetraamine                     |
| Hea                 | ethanolamine                                         | tn                 | trimethylenediamine                       |
|                     |                                                      | ur                 | urea                                      |

*Examples:* Li[B(NH<sub>2</sub>)<sub>4</sub>], lithium tetraamidoborate(1-) or lithium tetraamidoborate(III); [Co(NH<sub>3</sub>)<sub>5</sub>Cl]Cl<sub>3</sub>, pentaamminechlorocobalt(III) chloride or pentaamminechlorocobalt(2+) chloride; K<sub>3</sub>[Fe(CN)<sub>5</sub>CO], potassium carbonylpentacyanoferrate(II) or potassium carbonylpentacyanoferrate(3-); [Mn{C<sub>6</sub>H<sub>4</sub>(O)(COO)}<sub>2</sub>(H<sub>2</sub>O)<sub>4</sub>]<sup>-</sup>, tetraaquabis[salicylato(2-)]manganate(III) ion; [Ni(C<sub>4</sub>H<sub>7</sub>N<sub>2</sub>O<sub>2</sub>)<sub>2</sub>] or [Ni(dmg)] which can be named bis-(2,3-butanedione dioximato)nickel(II) or bis[dimethylglyoximato(2-)]nickel(II).

### 3.1.8 Addition Compounds

The names of addition compounds are formed by connecting the names of individual compounds by a dash (—) and indicating the numbers of molecules in the name by Arabic numerals separated by the solidus (diagonal slash). All molecules are cited in order of increasing number; those having the same number are cited in alphabetic order. However, boron compounds and water are always cited last and in that order.

*Examples:* 3CdSO<sub>4</sub> · 8H<sub>2</sub>O, cadmium sulfate—water (3/8); Al<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub> · K<sub>2</sub>SO<sub>4</sub> · 24H<sub>2</sub>O, aluminum sulfate—potassium sulfate—water (1/1/24); AlCl<sub>3</sub> · 4C<sub>2</sub>H<sub>5</sub>OH, aluminum chloride—ethanol (1/4).

## 3.2 PHYSICAL PROPERTIES OF PURE SUBSTANCES

**TABLE 3.2** Physical Constants of Inorganic Compounds

*Names* follow the IUPAC Nomenclature. Solvates are listed under the entry for the anhydrous salt. Acids are entered under Hydrogen and acid salts are entered as a subentry under hydrogen.

*Formula weights* are based upon the International Atomic Weights of 1993 and are computed to the nearest hundredth when justified. The actual significant figures are given in the atomic weights of the individual elements.

Each element that has neither a stable isotope nor a characteristic natural isotopic composition is represented in this table by one of that element's commonly known radioisotopes identified by mass number and relative atomic mass.

*Density* values are given at room temperature unless otherwise indicated by the superscript figure; for example,  $2.487^{15}$  indicates a density of 2.487 g/cm<sup>3</sup> for the substance at 15°C. A superscript 20 over a subscript 4 indicates a density at 20°C relative to that of water at 4°C. For gases the values are given as grams per liter (g/L).

*Melting point* is recorded in a certain case as 250 d and in some other cases as d 250, the distinction being made in this manner to indicate that the former is a melting point with decomposition at 250°C while in the latter decomposition only occurs at 250°C and higher temperatures. Where a value such as  $-6\text{H}_2\text{O}$ , 150 is given it indicates a loss of 6 moles of water per formula weight of the compound at a temperature of 150°C. For hydrates the temperature stated represents the compound melting in its water of hydration.

*Boiling point* is given at atmospheric pressure (760 mm of mercury or 101 325 Pa) unless otherwise indicated; thus  $82^{15\text{mm}}$  indicates that the boiling point is 82°C when the pressure is 15 mm of mercury. Also, subl 550 indicates that the compound sublimates at 550°C. Occasionally decomposition products are mentioned.

*Solubility* is given in parts by weight (of the formula weight) per 100 parts by weight of the solvent (i.e., percent by weight) and at room temperature. Another unit frequently used is grams per 100 mL of solvent (mL per 100 mL for liquids and gases). The symbols of the common mineral acids represent aqueous solutions of these acids.

### Abbreviations Used in the Table

|                                  |                      |
|----------------------------------|----------------------|
| a, acid                          | h, hot               |
| abs, absolute                    | hex, hexagonal       |
| abs alc, anhydrous ethanol       | HOAc, acetic acid    |
| acet, acetone                    | i, insoluble         |
| alk, alkali (aq NaOH or KOH)     | ign, ignites         |
| anhyd, anhydrous                 | L, liter             |
| aq, aqueous                      | lq, liquid           |
| aq reg, aqua regia               | MeOH, methanol       |
| atm, atmosphere                  | min, mineral         |
| BuOH, butanol                    | mL, milliliter       |
| bz, benzene                      | org, organic         |
| c, solid state                   | oxid, oxidizing      |
| ca., approximately               | PE, petroleum ether  |
| chl, chloroform                  | pyr, pyridine        |
| conc, concentrated               | s, soluble           |
| cub, cubic                       | satd, saturated      |
| d, decomposes                    | sl, slightly         |
| dil, dilute                      | soln, solution       |
| disprop, disproportionates       | solv, solvent(s)     |
| EtOAc, ethyl acetate             | subl, sublimates     |
| eth, diethyl ether               | sulf, sulfides       |
| EtOH, 95% ethanol                | tart, tartrate       |
| expl, explodes                   | THF, tetrahydrofuran |
| fcc, face-centered cubic         | v, very              |
| fctetr, face-centered tetragonal | vac, vacuum          |
| FP, flash point                  | viol, violently      |
| fum, fuming                      | volat, volatilizes   |
| fus, fusion, fuses               | <, less than         |
| g, gas, gram                     | >, greater than      |
| glyc, glycerol                   |                      |

### 4.1 ELEMENTS

---

The electronic configuration for an element's ground state (Table 4.1) is a shorthand representation giving the number of electrons (superscript) found in each of the allowed sublevels (*s*, *p*, *d*, *f*) above a noble gas core (indicated by brackets). In addition, values for the thermal conductivity, the electrical resistance, and the coefficient of linear thermal expansion are included.

**TABLE 4.1** Electronic Configuration and Properties of the Elements

| Name               | Symbol | Atomic number | Electronic configuration         | Thermal conductivity, $\text{W} \cdot (\text{m} \cdot \text{K})^{-1}$ at 25°C | Electrical resistivity, $\mu\Omega \cdot \text{cm}$ at 20°C | Coefficient of linear thermal expansion (25°C), $\text{m} \cdot \text{m}^{-1} (\times 10^6)$ |

4.2 IONIZATION ENERGY

TABLE 4.2 Ionization Energy of the Elements

The minimum amount of energy required to remove the least strongly bound electron from a gaseous atom (or ion) is called the ionization energy and is expressed in MJ · mol<sup>-1</sup>. Remember that 96.485 kJ = 1.000 eV = 23.0605 kcal. In Table 4.2 the successive stages of ionization are indicated by the heading of each column: I denotes first spectra arising from a neutral atom; viz.,

II, second spectra from singly ionized atoms, and so on for successive stages of ionization.

| At.<br>no. | Element | Spectrum (in MJ · mol <sup>-1</sup> ) |       |        |        |        |        |

**TABLE 4.3** Ionization Energy of Molecular and Radical Species

This table gives the first ionization potential in MJ · mol<sup>-1</sup> and in electron volts. Also listed is the enthalpy of formation of the ion at 25°C (298 K).

*Compounds containing carbon*

| Species            | Ionization energy         |                   | $\Delta_f H$ (ion)<br>in kJ · mol <sup>-1</sup> |
|--------------------|---------------------------|-------------------|-------------------------------------------------|
